Identical bills are pending in the Senate and the House of Representatives to implement the recommendations contained in the report recently submitted to President Truman by Dr. Vannevar Bush, director of the Office of Scientific Research and Development, and other collaborating scientists, outlining a suggested federal program to promote scientific research. The Senate bill, S. 1285, introduced on July 19 by Senator Magnuson of Washington, was referred to the Senate Committee on Commerce, of which Senator Bailey of North Carolina is chairman. The House bills, H. R. 3852, introduced on July 19 by Representative Mills of Arkansas, and H. R. 3860, introduced on July 20 by Representative Randolph of West Virginia, have been referred to the House Committee on Interstate and Foreign Commerce, of which Representative Lea of California is chairman.

On July 23 Senator Kilgore of West Virginia, for himself and Senator Johnson of Colorado, and Senator Pepper of Florida, introduced S. 1297, which embodies principles which the Subcommittee on War Mobilization of the Senate Military Affairs Committee, on the basis of extensive studies made over the past two years, has set up as desirable in any legislation designed to meet the postwar scientific needs of the nation. The bill is pending in the Senate Committee on Military Affairs, of which Senator Thomas of Utah is chairman.

Representative May of Kentucky has introduced another bill relating to scientific research, H. R. 3440. This bill would authorize an appropriation of not to exceed $8,000,000 annually to enable the National Academy of Sciences, through a research board for national security consisting of representatives of the Army, Navy and civilians of outstanding accomplishments, to provide for scientific research and advancement determined by the board to be desirable in the interest of national security. It has passed the House of Representatives and is pending in the Senate Committee on Naval Affairs.

Another pending bill, S. 825, was introduced by Senator Byrd of Virginia on April 4 and was referred to the Senate Committee on Naval Affairs, of which Senator Walsh of Massachusetts is chairman. It would create a Research Board for National Security to include representatives of the Army and Navy, the chairman of the National Advisory Committee for Aeronautics and civilian scientists, engineers or industrialists. It will be the duty of the board to formulate programs of scientific research and development relative to problems of national security. The term "science" as used in the bill includes the employment of scientific methods of analysis, experiment and test in any "branch of science or technology, including engineering, medicine, dentistry, psychology and biology." This bill was favorably reported to the Senate July 28, with amendments.

Another bill has been introduced in the Senate by Senator Fulbright, Arkansas, S. 1248. It proposes to establish a Bureau of Scientific Research in the Department of Commerce "to aid, encourage, and protect the research and enterprise of inventors, scientists, technicians, scientific and educational institutions, and research laboratories engaged in scientific and technical work, and to make their resultant discoveries and data more readily available, without discrimination, to all sections of industry, agriculture, and the public in order to promote full employment and higher standards of living." This bill is pending in the Senate Committee on Commerce, of which Senator Bailey, North Carolina, is chairman.

With the exception of the three bills designed to implement the recommendations contained in the Bush report, these proposals differ in many details; that fact was given recognition by Senator Kilgore at the time he introduced his bill. After referring to the other pending legislation, he expressed the hope that arrangements could be made for joint hearings "so that the issues presented by these different bills can be clarified and agreement reached at an early date on the scope of research needed in the interest of national security and also on the details of organization and administration so essential to the success of any national program of scientific research."

There follows a factual analysis of the Magnuson-Mills-Randolph bill and the Kilgore bill.

THE MAGNUSON-MILLS-RANDOLPH BILL

This legislation would create a National Research Foundation as an independent agency in the executive branch of the government to secure the full development and application of the nation's scientific and technical resources for national defense, prosperity, health and welfare.

Administrative Board.—The powers and duties of the foundation will be exercised by a board of nine members appointed by the President without regard to political affiliations and solely on the basis of their demonstrated interest in and capacity to promote the purposes of the foundation. The board will be authorized to employ a director at a salary of $15,000 a year, who will be the principal executive officer of the foundation. Two deputy directors may be appointed by the director, each of whom will receive compensation at the rate of $12,000 a year. The members of the board will serve without compensation but will be allowed actual and necessary traveling and subsistence expenses when engaged, away from home, in the duties of their office.

Divisions Within Foundation.—Within the foundation there will be a minimum of five divisions as follows: (1) a Division of Medical Research to carry out programs relating to research in biologic science, including medicine and the related sciences; (2) a Division of Physical Sciences to carry out programs relating to research in the mathematical and physical sciences; (3) a Division of National Defense to carry out programs relating to scientific research on military matters; (4) a Division of Scientific Personnel and Education to carry out the program relating to the grant of scholarships and fellowships in the mathematical, physical and biologic sciences, and (5) a

Division of Publications and Scientific Collaboration to carry out programs relating to the public dissemination of scientific information among scientists. Additional divisions may be created by the board.

Committees Within Divisions.—In each division will be a committee of not less than five members appointed by the board after receiving recommendations from the National Academy of Sciences. The committee within the Division of National Defense, in addition, will include a member designated by the Secretary of War and a member designated by the Secretary of the Navy.

The appointed members will receive compensation at the rate of $50 a day while engaged in the business of the foundation plus expenses when engaged, away from home, in the duties of their office. Each committee will make recommendations to and advise and consult with the board and the director with respect to matters of its division. Additional powers and duties may be devolved on the committees by the board.

Powers and Duties of the Foundation.—In carrying out the purposes of the bill, the foundation will be authorized and directed:

(1) to develop and promote a national policy for scientific research and scientific education;

(2) to initiate and support basic scientific research and scientific development in the mathematical, physical and biologic sciences through contracts, grants or other forms of assistance;

(3) to initiate and support scientific research and scientific development on matters relating to the national defense through contracts, grants or other forms of assistance;

(4) to discover and develop scientific talent, particularly in American youth;

(5) to grant scholarships and fellowships in the mathematical, physical and biologic sciences;

(6) to foster the interchange of scientific information among scientists in this country and abroad; and

(7) to correlate the foundation's scientific research and scientific development programs with those undertaken by public and private research groups.

Authority of Foundation.—The foundation will be specifically authorized (1) to prescribe such rules and regulations as it deems necessary; (2) to enter into contracts, or amendments or modifications of contracts without legal consideration, without performance or other bonds in the case of all contracts which relate to scientific research or scientific development; (3) to make advance, progress and other payments which relate to scientific research or scientific development; (4) to acquire by purchase or otherwise, hold and dispose of by sale, lease, loan or otherwise real and personal property of all kinds necessary for or resulting from scientific research or scientific development without regard to the provisions of law relating to the acquisition, holding or disposition of property by the United States; (5) to receive and use funds donated by others, provided such funds are donated, without other restriction, in furtherance of one or more of the general purposes of the foundation; (6) to publish or arrange for the publication of scientific and technical information so as to further the full dissemination of information of scientific value consistent with the national interest; (7) to accept and utilize the services of voluntary and uncompensated personnel and to pay the actual and necessary traveling and subsistence expenses, including in lieu of subsistence per diem at a rate not in excess of $10, of such personnel incurred in the course of such services; (8) to prescribe the extent to which vouchers for funds expended under contracts for scientific research and development shall be subject to itemization or substantiation prior to payment, without regard for the limitations of other laws relating to the expenditure of public funds and accounting therefor; (9) to establish a National Science Reserve in which will be enrolled all those who receive scholarships and fellowships in science and medicine from the foundation. Members of the National Science Reserve will be available for call into the service of the government for scientific and technical work in time of war or other national emergency as declared by the Congress or proclaimed by the President.

Appropriations.—The bill will authorize to be appropriated annually to the foundation such sums as may be necessary to carry out its provisions. Funds appropriated for the foundation will, if obligated during the fiscal year for which appropriated, remain expendable for a period of four years. After such a four year period, the unexpended balances will revert to the treasury.

General Provisions.—The bill specifically provides that the foundation shall not itself operate any scientific or technical facilities of its own.

There will be transferred to the foundation all powers, functions and duties of the Office of Scientific Research and Development and its constituent committees. All personnel, property, records, funds, contracts, assets and liabilities of the Office of Scientific Research and Development, and of its constituent committees, will also be transferred to the foundation. This transfer will take effect at such time as the President directs.

Members of the board and members of the committees within the divisions may engage in private and gainful employment, but no compensation for such employment may be received in any form by any such member (1) from any profit-making organization which receives funds under contract, or otherwise, within the cognizance of the division or divisions of the foundation with which such member is concerned or (2) in respect of any particular matter which directly involves the foundation or in which the foundation is directly interested.

The director will be authorized to appoint and fix the compensation of necessary personnel, subject to the provisions of the civil service laws and regulations and the Classification Act of 1923. Technical and professional personnel may be employed without regard to the provisions of the Classification Act. The director, the deputy directors and the members of the committees within the divisions will also be appointed without reference to the civil service laws or the Classification Act.

The foundation will be required to submit an annual report in writing to the President and the Congress and the bill, if enacted, will be cited as the "National Research Foundation Act of 1945."

THE KILGORE BILL

The title of the Kilgore bill, S. 1297, indicates its purpose, namely, to promote the progress of science and the useful arts, to secure the national defense and to advance the national health and welfare.

National Science Foundation.—An independent agency of the federal government to be known as the National Science Foundation will be created. It will be administered by a director appointed by the President, by and with the advice and consent of the Senate. His salary will be $15,000 a year.

The director will be required to consult and advise with a National Science Board on all matters of major policy or program. The board will consist of the director as chairman, the heads of the Departments of War, Navy, Justice, Interior, Agriculture, Commerce and Labor, and the Federal Security Agency or their designees, plus eight public members appointed by the President by and with the advice and consent of the Senate.

Promotion of Research and Development.—The foundation will be required to give particular attention to promoting research and development activities relating to (1) national defense, (2) health and medicine, (3) the basic sciences, (4) the conservation, development and use of the natural resources of the nation, (5) the development of methods and processes beneficial to small business enterprises and (6) the adaptation to peacetime use of wartime research and facilities.

Not less than 20 per cent of the funds to be made available to the foundation for research and development activities will

be expended for research and development in each of the following fields: (1) national defense and security and (2) health and medicine.

The bill requires the foundation to consider the desirability of utilizing facilities available in departments and agencies of the federal government, state and local governments, educational institutions, research institutions, private industrial organizations, and individual scientists particularly qualified to carry out such projects. Not less than 50 per cent of the total funds appropriated by the Congress for research and development activities under the bill must be expended for engaging the facilities of qualified nonprofit educational institutions and research institutions.

Committees Within Foundation.—A minimum of two committees within the foundation are to be established: (1) a Research Committee for National Defense consisting of a chairman to be appointed by the President by and with the advice and consent of the Senate, whose salary will be $12,000 a year, and nine members at large, three to be designated by the Secretary of War, three by the Secretary of the Navy and three by the director with the advice and approval of the board; and (2) a Research Committee for Health and the Medical Services, consisting of a chairman appointed by the President by and with the advice and consent of the Senate, whose salary will be $12,000 a year, and nine members at large, of whom three shall be designated by the administrator of the Federal Security Agency and six by the director with the advice and approval of the board.

The members at large to be appointed by the Secretaries of War and the Navy and the administrator of the Federal Security Agency may be civilian or military employees of the government or public members. The director will be required to advise with these two committees with respect to the formulation of overall research and development programs in the fields of national defense and health and medicine and must secure the approval of the committees with respect to the determination of specific projects and the selection of specific facilities.

Additional advisory committees may be set up by the director, and members of such committees will be appointed by the director by and with the advice and consent of the board and, in appointing such members, the director may request appropriate national scientific organizations to submit panels of candidates from which he may make his selection.

Scholarships and Fellowships.—The foundation will be authorized to grant scholarships and fellowships to persons showing special aptitude, for one year's study at a nonprofit institution of higher education or other nonprofit institution. Scholarships and fellowships are to be renewable for a period up to five years at the option of the foundation.

Survey of Federal Scientific Activity; Dissemination of Research Findings.—The foundation will be required to make and maintain a comprehensive survey of federally financed research and development activities. Any agency engaged in such activities will be required, on request by the director, to furnish whatever data and reports may be needed. The foundation must evaluate such survey data and make recommendations to the President and the agencies concerning improvements.

Each contracting organization or institution or individual, as a condition to receiving financial support from the foundation, will be required to make available full data on all inventions, discoveries and other significant findings. The foundation will be directed to collect, edit, publish and disseminate pertinent data on all inventions, discoveries and other findings resulting from federally financed research and development activities. It must take such steps as necessary to disseminate such data to the public, including the preparation of abstracts, translations, bibliographies and microfilm reproductions of research and development reports and publications.

The foundation will be required to do what it can to eliminate restraints on the free expression of scientific truths and to insure ample freedom in the exercise of creative talents and in the development of promising new ideas in connection with all research and development projects promoted, financed or otherwise supported by the federal government.

All materials or equipment purchased or furnished by federal funds in connection with research and development projects, and any invention, discovery or finding resulting from such federally financed projects shall be the property of the federal government.

Restriction on Dissemination of Information.—The Defense Committee must declare secret or restricted any scientific or technical information, data, patents, inventions or discoveries in or coming into the possession or control of the foundation, the secrecy or restriction of which the President or his designee or designees certify as being essential in the interest of national defense.

Patents.—The director will be required to patent all significant inventions or discoveries resulting from research and development projects. Any citizen, corporation or other organization desiring to use any invention, discovery or patent which is or may hereafter become the property of the United States will, on proper application, be granted without further limitation a nonexclusive license for which there will be no charge. The foundation will be required, however, to refuse to grant a license to any applicant on a finding in writing by the Department of Justice to the director that the granting of such license will tend to promote or result in a monopoly or a practice which is in restraint of trade.

Appropriations.—Such sums as may be necessary to carry out the provisions of the bill may be annually appropriated by the Congress to the foundation. In addition, the foundation may solicit and receive financial grants, personal services and any other aid furthering scientific and technical progress, may enter into contracts and make expenditures for personnel, equipment and services as it may deem necessary. The foundation may not itself or through its own employees operate any laboratories, pilot plants or other such scientific or technical facilities which it may acquire.

Employment of Personnel.—The director will be authorized to appoint and fix the compensation of necessary personnel. Appointments and compensation shall be made in accordance with the provisions of the civil service laws and the Classification Act, except that technical and professional personnel may be employed without regard to such laws.

Public members of the board and of any advisory committee will serve without remuneration except for per diem allowances, transportation and other necessary expenses incurred. No employee of the foundation or member of any advisory committee may participate in any decision or recommendation affecting his personal financial interest or the activities of any organization in which he has a financial interest or by which he is employed.

"Research and Development" Defined.—These terms are declared to mean not only theoretical analysis, exploration and experimentation but also the extension of investigative findings and theories of a scientific or technical nature into practical application, including the preparation of plans, specifications and standards for various goods and services, the undertaking of related economic and industrial studies, the experimental production and testing of models, and the building and operation of pilot plants.

Miscellaneous.—The director must render an annual report in writing to the President and to Congress, summarizing the activities of the foundation and containing such recommendations as he may deem appropriate. The foundation will be granted the free use of the mails. As used in the bill, the term "federally financed" means financed in whole or in part by the federal government. The bill, if enacted, will be cited as the "National Science Foundation Act of 1945."

THE MATERNAL AND CHILD WELFARE ACT OF 1945

An Analysis Prepared by the Bureau of Legal Medicine and Legislation, American Medical Association

Senator Pepper, Florida, for himself and nine other members of the Senate Committee on Education and Labor, has introduced a bill, S. 1318, to provide for the general welfare by enabling the several states to make more adequate provision for the health and welfare of mothers and children and for services to crippled children and for other purposes. Joining Senator Pepper in sponsoring this legislation were Senator Walsh, Massachusetts; Senator Thomas, Utah; Senator Hill, Alabama; Senator Chavez, New Mexico; Senator Tunnell, Delaware; Senator Guffey, Pennsylvania; Senator LaFollette, Wisconsin; Senator Aiken, Vermont, and Senator Morse, Oregon. The bill was referred to the Senate Committee on Education and Labor, of which Senator Murray, Montana, is chairman.

An appropriation of $100,000,000 will be authorized for the fiscal year ending June 30, 1946: $50,000,000 earmarked for maternal and child health services, $25,000,000 for services for crippled children, $20,000,000 for child welfare services and $5,000,000 for expenses necessary to enable the Children's Bureau to administer the provisions of the bill and to develop and promote effective measures for carrying out its purposes, including "studies, demonstrations, investigations and research, the training of personnel for federal, state and local service, and the payment of salaries and expenses of personnel detailed at the request of state agencies to cooperate with and assist such agencies" in carrying out the objectives of the legislation. Thereafter such sums will be made available as the Congress shall decide.

The bill, which Senator Pepper has described as "a modest beginning," has five titles:

TITLE I. MATERNAL AND CHILD HEALTH SERVICES

The stated objectives of this title are to provide and maintain services and facilities to promote the physical and mental health of mothers during the maternity period and of children, including medical, nursing, dental, hospital and related services and facilities required for maternity care, preventive health work and diagnostic services for children, school health services, care of sick children, and correction of defects and conditions likely to interfere with the normal growth and development and the educational progress of children. The development of more effective measures for carrying out the purposes of the title is contemplated, including demonstrations and the training of personnel for state and local maternal and child health services.

Of the total appropriation to be made available under this title, $5,000,000 will be allotted by the Secretary of Labor to the several states, and allotments must be matched dollar for dollar by state or state and local funds. In determining what amount each state shall be allotted, the Secretary of Labor will take into consideration the number of children under 21 years of age in such state in relation to the total number of children under 21 years of age in the United States.

The remainder will be allotted to the states by the Secretary of Labor after taking into consideration for each state such factors as the number of mothers and children under 21 years of age in the state for whom the services and care are to be made available, and the cost of furnishing such services and care to them, the special problems of maternal and child health and the financial need of the state for assistance in carrying out the state plan.

Approval of State Plans.—Allotments will be paid to those states whose plans for developing programs and for providing care and services have been approved by the chief of the Children's Bureau. In order for a plan to be approved by the chief of the Children's Bureau, it must:

1. Provide for financial participation by the state.

2. Provide for a statewide program or for extension of the program each year so that it will be in effect in all political subdivisions by July 1, 1955.

3. Provide that services and facilities shall be available to all mothers and children in the state or locality who elect to participate in the benefits of the program. There must be no discrimination because of race, creed, color or national origin, and no residence requirements.

4. Provide for the administration of the plan by the state health agency, or for the supervision of the administration of the plan by the state health agency, and for appropriate coordination of the plan with the general public health and medical care program of the state health agency which will be authorized to develop agreements or cooperative arrangements with other state or local public agencies whose functions include the provision of services similar or related to those furnished under the state plan.

5. Be made part of the state plan for maternal and child health services submitted in accordance with the provisions of title V, part 1, of the Social Security Act.

6. Provide effective methods of administration, including the establishment and maintenance of personnel standards on a merit basis, standards for professional personnel rendering medical, dental, nursing and related types of care or service, and standards for hospital and other institutional care and services. Standards are to be established by the state health agency after "consultation" with professional advisory committees appointed by the state health agency. Mothers and children, or persons acting in their behalf, will be permitted to select, from among those meeting standards prescribed by the state health agency, the physician, hospital, clinic or health service agency of their choice. Where no such selection is made, the state plan must set forth the method by which the care will be made available. The bill provides that the physician, hospital, clinic or health service agency selected may refuse to accept the case.

A state plan must provide for adequate remuneration for the persons and institutions providing medical care and related services, must provide opportunities for postgraduate training of professional and technical personnel, and for such use of health centers, hospitals, clinics and health service agencies, public and voluntary, as will achieve the satisfactory distribution and coordination of preventive, diagnostic, consultative and curative services provided by general practitioners, specialists, public health personnel, laboratories and others.

A state plan must provide payments to individual physicians for care furnished under this title on a per capita, salary, per case or "per session" basis or, in the case of consultations or emergency visits, on a fee-for-service basis. A state plan must furthermore provide for the purchase of care from public or voluntary hospitals and other health service agencies included under the state plan on a basis related to cost for providing the care.

7. Provide for adequate dissemination of information with regard to the maternal and child health services to be made available under this title.

8. Provide for reports to the chief of the Children's Bureau.

9. Provide for cooperation with medical, health, hospital, nursing, education and welfare groups and organizations in the state.

10. Provide (*a*) for a general advisory council appointed by the state health agency and composed of members of the professions or agencies, public and voluntary, that furnish care or services under the state plan, and other persons representing the public who are informed on the need for and problems related to the provision or receipt of maternal or child health services and medical care of mothers and children, and (*b*) for technical advisory committees appointed by the state health agency composed of medical and other professional groups concerned with the administration or operation of a state plan. If the state health agency administers a program for services to crippled children, the same general advisory council shall serve both the maternal and child health and the crippled children programs.

11. Provide for a fair hearing before the state health agency for any mother or other person acting in behalf of a child whose claim for services is denied or for any physician or other person, organization or institution participating or desiring to participate in furnishing services or facilities under the plan.

Federal Advisory Committees.—The chief of the Children's Bureau will formulate general policies for the administration of this title after "consultation" with a conference of state health officers and an advisory committee composed of professional and public members and, as necessary, technical advisory committees which "he" shall appoint.

TITLE II. SERVICES FOR CRIPPLED CHILDREN

The stated objectives of this title are to enable each state to provide and maintain services and facilities for the care and treatment of children who are crippled, otherwise physically handicapped or suffering from conditions which lead to crippling or physical handicaps, including services for locating such children, for providing medical, surgical, corrective and other services and care, and facilities for diagnosis, hospitalization and after-care for such children. Demonstrations and the training of personnel for state and local crippled children's services are contemplated.

Out of the total appropriation authorized under this title, the Secretary of Labor will allot to each state such part of $2,500,000 as he finds that the number of children under 21 years of age in such state bore to the total number of children under 21 years of age in the United States in the latest calendar year for which the Bureau of the Census has available statistics. Such allotments must be matched dollar for dollar by state or state and local funds made available for services for crippled children.

The remainder of the appropriation will be allotted to the states by the Secretary of Labor after taking into consideration for each state such factors as (1) the number of crippled children under 21 years of age in the state for whom services and care are to be made available and the cost of furnishing such services and care to them, (2) the special problems of crippled children and (3) the financial need of the state for assistance in carrying out the state plan.

Approval of State Plans.—Allotments will be made to the states which have submitted to and had approved by the Children's Bureau state plans for developing programs for crippled children. As in the case of state plans developed under title I, the bill indicates the contents a state plan must have to be approved. Such a state plan for services for crippled children must meet essentially the same requirements specified for plans developed under title I except that, if a state agency other than the state health agency is designated by state law to administer the program for crippled children, that agency may continue as the state administrative agency until July 1950, after which the state health agency must have jurisdiction. Services to be provided under this title must be available to all crippled children without regard to financial status, race, creed, color or national origin, and there may be no residence requirement. Individual physicians will be paid as indicated in title I, except that title II makes no provision for payment on a per capita basis.

Federal Advisory Committees.—The chief of the Children's Bureau will formulate all general policies for the administration of this title after "consultation" with (1) a conference of executive officers of state agencies administering the program for crippled children under this title and (2) an advisory committee composed of professional and public members and, as necessary, technical advisory committees, which "he" shall appoint.

TITLE III. CHILD WELFARE SERVICES

The declared purpose of title III is to assist each state public welfare agency to develop effective statewide child welfare programs and measures, including the training of personnel, for extending and strengthening public child welfare services, and for providing suitable care and protection for children without parental care and supervision, and children who are dependent, neglected or delinquent, or in danger of becoming neglected or delinquent.

For each of the fiscal years ending June 30, 1946 and June 30, 1947 the Secretary shall allot to each state such part of $10,000,000, and for the fiscal year ending June 30, 1948 and for each fiscal year thereafter such part of three fourths of the total amount appropriated for child welfare services as he finds that the number of children under 21 years of age in such state bore to the total number of children under 21 years of age in the United States in the latest year for which the Bureau of the Census has available statistics. Such allotments must be matched dollar for dollar by state or state and local funds made available for child welfare services.

For the fiscal year ending June 30, 1946 and for each fiscal year thereafter the remainder of the sum appropriated for child welfare services will be allotted to the several states by the Secretary of Labor, taking into consideration for each state such factors as (1) the number of children under 21 years of age in the state for whom child welfare services are to be made available and the cost of providing such services and care to them, (2) the special problems of child welfare and (3) the financial need of the state in carrying out the state plan.

Approval of State Plans.—Allotments will be made to states which have submitted to and had approved by the Children's Bureau state plans for child welfare services. The chief of the Children's Bureau will be required to approve any state plan which meets the following conditions:

(1) Financial participation by the state.

(2) A statewide program, including at least guidance and social service to or in behalf of children who are dependent, neglected or delinquent, or in danger of becoming neglected or delinquent, or for the extension of the program each year so that such guidance and service will be available to all children in need thereof, in all political subdivisions of the state not later than July 1, 1955.

(3) Services and care furnished under the plan must be made available to all children without regard to financial status, race, creed, color or national origin, and without residence requirements.

(4) Administration or supervision of the plan by the state public welfare agency and coordination of the plan with the general public welfare program of the state public welfare agency which will be authorized to develop agreements or cooperative arrangements with other state agencies whose functions include the provision of services related to the services furnished under the state plan.

(5) The state plan must be made a part of the plan for child welfare services submitted in accordance with the provisions of title V, part 3, of the Social Security Act.

(6) The plan must provide such methods of administration as are found by the chief of the Children's Bureau to be necessary for the proper and efficient operation of the plan, including methods relating to the establishment and maintenance of personnel standards on a merit basis.

(7) The state public welfare agency must make such reports in such form and containing such information as the chief of the Children's Bureau may from time to time require.

(8) Appropriate cooperation must be provided for with state and local agencies, public and private, concerned with child health, education, child welfare and related subjects.

(9) The plan must provide for a program of training for personnel rendering child welfare services.

Definitions.—As used in this title, the term "child welfare services" means (1) guidance and social service to or on behalf of children who are dependent, neglected or delinquent, or in danger of becoming neglected or delinquent; (2) placement, supervision and maintenance of children in foster family homes; (3) temporary care of children who are dependent, neglected or delinquent, or in danger of becoming neglected or delinquent, especially in areas where children would otherwise be detained in jail or would be deprived of necessary protection and shelter or study of their special needs; (4) specialized services needed to strengthen and improve the programs of public institutions caring for children; (5) care in foster homes or day care centers for children whose mothers are employed or whose home conditions require care outside their own homes during any part of the twenty-four hour day, including services necessary to

assure proper use of day care facilities and to safeguard children receiving care; (6) payment of the cost of returning nonresident children to their own communities; if such return is desirable and the cost thereof cannot otherwise be met, and (7) cooperation with state and community agencies in improving conditions affecting the welfare of children.

TITLE IV. ADMINISTRATION

If the Secretary of Labor finds that in the administration of any plan approved under the bill there is a failure to comply substantially with any requirement specified as necessary for inclusion in a state plan, he may withhold further allotments.

The Children's Bureau will be directed to make and aid the financing of such studies, demonstrations, investigations and research as will promote the efficient administration and operation of the legislation.

TITLE V. GENERAL PROVISIONS

The chief of the Children's Bureu, subject to the approval of the Secretary of Labor, will make and publish such rules and regulations as are necessary to the efficient operation of the legislation and will be required to submit each year to the Congress a full report of such administration.

As used in the bill, the term "state" means any state of the United States, the District of Columbia or any territory or possession of the United States.

Medical Legislation

MEDICAL BILLS IN CONGRESS

International Health Organization

Senator Pepper, Florida, for himself and Senator Wagner, New York, Senator Murray, Montana, Senator Capper, Kansas, Senator Ball, Minnesota, and Senator Smith, New Jersey, has introduced S. J. Res. 89 relating to the formation of an International Health Organization. After referring to the fact that the United Nations Conference at San Francisco adopted a recommendation to convene a conference to draw up the statutes of an International Health Organization, this joint resolution expresses the sentiment of Congress that there should be a speedy convening of such conference and the early formation of such an International Health Organization. If the joint resolution is adopted, the President, on behalf of the government of the United States, will be authorized to take immediate steps to hasten the convening of the conference and the formation of the organization.

Scientific Research

Senator Kilgore, West Virginia, for himself and Senator Johnson, Colorado, and Senator Pepper, Florida, proposes by S. 1297 to promote the progress of science and useful arts, to secure the national defense and to advance the national health and welfare. This bill would create a National Science Foundation to promote scientific research as an independent agency of the federal government.

Another bill relating to the same subject matter has been introduced by Senator Fulbright, Arkansas, S. 1248. This bill would create a Bureau of Scientific Research in the Department of Commerce.

The Byrd bill, S. 825, proposing to establish a Research Board for National Security, was favorably reported to the Senate, July 28.

Miscellaneous

A bill proposing an annual appropriation of not to exceed $100,000,000 to provide assistance to the states in establishing, maintaining, operating and expansion of school lunch programs, S. 962, has been reported to the Senate with recommendation that it pass.

Senator Langer, North Dakota, proposes by S. 1262 that the American Red Cross be authorized to award meat and fat ration tokens, shoe ration coupons and sugar ration coupons to persons donating blood to the American Red Cross for use by members of the armed forces.

Another bill introduced by Senator Langer, North Dakota, S. 1332, would provide maternity leave for government employees.

H. R. 3761, introduced by Representative Welch, California, proposes to amend in several respects the Longshoremen's and Harbor Workers' Compensation Act. One of the amendments would authorize an injured employee to select to treat him any physician authorized by the commission to render medical care to beneficiaries of the act. The commission would be authorized to establish such panels of qualified physicians, surgeons, specialists, consultants, "laboratory x-ray or other technicians," compensation medical bureaus and laboratories as may be necessary and would be authorized to establish schedules of fees to be charged by those rendering services to beneficiaries.

Official Notes

ELECTRICAL TRANSCRIPTIONS ON PUBLIC HEALTH

Effective August 14 the Bureau of Health Education offers an additional series of electrically transcribed radio programs for use by local medical societies or by local health agencies approved by such local societies.

The new series of health platters is entitled Guardians of Your Health. It consists of interviews and round table discussions featuring thirty-three public health authorities, including health officers of cities and states, laboratory directors, nurses and federal health officials. The theme of the series is medical and public health cooperation for the better health of the nation. The programs were prepared under the supervision of the Bureau of Health Education; scripts were written by Harriet Hester, who also interviewed the speakers; each program is summarized by Dr. W. W. Bauer, Director of the Bureau of Health Education. The titles and speakers are as follows:

1. Doctors Guard Your Health: Haven Emerson, M.D., New York; W. W. Bauer, M.D., Chicago.

2. Health in Your Town: M. R. French, M.D., Paw Paw, Mich.; Gertrude Cromwell, R.N., Des Moines, Iowa; Major Joel I. Connolly, Chicago.

3. The Healthy State: A. J. Chesley, M.D., St. Paul; Stanley Osborn, M.D., Hartford, Conn.

4. Guarding the Nation's Borders: Thomas Parran, M.D., Surgeon General, James P. Leake, M.D., C. C. Applewhite, M.D., U. S. Public Health Service.

5. Health in Our Hemisphere. John A. Ferrell, M.D., New York; Hugh S. Cumming, M.D., Pan American Sanitary Bureau.

6. Health in the Schools: Ruth Grout, Ph.D., Minneapolis; Charles C. Wilson, M.D., New York.

7. Sanitation—An Unfinished Job: H. G. Callison, M.D., South Carolina; F. C. Beelman, M.D., Kansas; Huntington Williams, M.D., Baltimore.

8. Guarding the Food Front: P. A. Dunbar, Ph.D., U. S. Food and Drug Administration; Willard H. Wright, M.D., U. S. Public Health Service.

9. Trained Public Health Workers: William P. Shepard, M.D., San Francisco; Agnes Fuller, R.N., New York.

10. The Public Health Laboratory: W. D. Stovall, M.D., Madison, Wis.

11. Controlling Contagious Diseases: Carl A. Wilzbach, M.D., Cincinnati; Thurman B. Rice, M.D., Indianapolis; Commander Dean F. Smiley, U. S. Navy.

12. Popular Health Crusades: Charles E. Lyght, M.D., Don W. Gudakunst, M.D., Walter F. Clarke, M.D., Philip Platt, C.P.H., New York.

13. Health Education: Donald Armstrong, M.D., New York; Thomas G. Hull, Ph.D., Chicago; Lester Taylor, M.D., Cleveland.

These platters are available on loan by application to the Bureau of Health Education. The series will be lent only as a whole and for broadcasting purposes only. There is no charge to the local group except payment of return shipping costs. All local broadcasting arrangements must be made by local groups. Scripts accompany platters; but material to be offered to listeners, if such offers are to be made, must be provided locally.

Washington Letter

(From a Special Correspondent)

Aug. 6, 1945.

War Department to Restaff Medical Units Deployed to Pacific

The War Department has announced that plans are being worked out to restaff all Army Medical Department units deployed through the United States to the Pacific with doctors who have not seen overseas service. It is also revealed that 1,000 medical officers have been requisitioned from Europe for return at the end of this month to relieve a shortage of doctors in army hospitals in this country. Recently Secretary Stimson informed Chairman Thomas of the Senate Military Affairs Committee that 7,000 doctors would be released during the next nine months for return to civilian practice. Senators have protested about the "leisurely attitude" of the Army toward the demobilization of doctors. Only 900 have been discharged since January 1. The Army explains that there will be an initial lag in the discharge of doctors over other officers because sick and wounded soldiers remain in hospitals long after the fighting is over. The War Department denies that the Army is overstaffed with medical officers by pointing out that personnel is slightly below the 45,000 ceiling set in September 1944, which was 5,000 below the ceiling set for the Army by the War Manpower Commission. The present ceiling will be cut by 7,000 in ensuing months and is said to be far under requirements set forth by Congress in its ratio of 6.5 doctors per thousand men.

Veterans Administration Medical Staff to Expand

Expansion of the entire Veterans Administration medical staff, professional and lay, is predicted in the next few years as more veterans of this war require hospitalization. Gen. Omar N. Bradley takes over the agency on August 15, heading one of the few federal agencies that will grow rather than shrink after the war. The administration had more than 63,000 at last report and it needs 2,000 nurses at once and 600 more doctors by the end of October. When the war ends, between 7,000 and 8,000 soldiers who are on detached service as orderlies, attendants, clerks and in other capacities will have to be replaced by civilians. Actuaries say that veterans' hospitals must be staffed to take care of 300,000 patients within twenty years. Considerable legislation, affecting veterans as well as reorganization of the agency, awaits recommendations of General Bradley when Congress returns from its recess early in October.

Proposed Control of Newly Discovered Synthetic Drugs

The Senate has passed and sent to the House legislation to allow the Treasury Narcotic Bureau to control the sale of numerous newly discovered synthetic drugs which are said to have the "dangerous, habit forming" qualities of morphine and cocaine. The present procedure requires that Congress pass a special law each time a new drug of this sort is placed on the market before the Treasury can issue regulations to control it. Chairman Walter F. George of the Senate Finance Committee said that the Treasury expected a number of new habit forming synthetic drugs to appear on the market any day. The proposed law would enable the Narcotic Bureau to act at once "before any great quantity" reaches the market, he said.

Further Requests for Better Artificial Limbs for Wounded Servicemen

Severe criticism of the artificial arms and legs which the government is supplying to wounded service men has been expressed editorially in Washington newspapers and in others throughout the country. The Washington *Daily News* said editorially "We don't know what's wrong or what specific steps should be taken to remedy the situation. We do know that some of the men who have given their arms and legs for this country feel deeply that they are not getting the proper appliances. This country, which has made efficient airplanes and rocket bombs, apparently hasn't produced workable artificial arms and legs." Newspaper comments further state that what the amputees want now is action, through coordinated research and effort, rather than a multiplicity of suggestions on what might be done. One newspaper said that "maybe we ought to have a Baruch report on artificial arms and legs. Not necessarily made by Mr. Baruch—perhaps by some leading doctors or medical institution, like the Mayo Clinic or Johns Hopkins." The government has appealed for new ideas on how to make better artificial arms and legs for wounded servicemen. An official of the National Inventors Council, a government agency set up to receive suggestions to help win the war, said "We need more ideas from the general public as well as inventors. The American people have always been inventive and ingenious. Maybe there is some plan not yet tried which would make better limbs." Research is now being conducted by the Army and Navy and in some private laboratories under auspices of the National Research Council. Several recently made suggestions are now being acted on.

Army Doctors in Pacific Find Replacements Delayed

Although the Army says it is relieving as speedily as possible its doctors who have been stationed for long periods in the Pacific, it is disclosed that delayed replacements from Europe have prolonged service of these medical officers. Some have been in the Pacific theater for as long as three years, enduring hardships and bad climate. The Surgeon General's Office estimates that it requires four to five months for a doctor to be shipped from Europe, furloughed in the United States and moved on to the Pacific on assignment relacement. A month is required after a doctor is relieved from permanent duty in Europe until he boards a home bound ship, and on reaching this country two weeks must elapse before he starts his thirty day furlough. Travel time then has to be figured for movement to a West Coast shipping center. Another thirty days is required crossing the Pacific to reach the ultimate destination. Then, before the Pacific Army doctor can leave for home, two weeks must be spent to acquaint the new man with the job.

Flood Interrupts Research on Tropical Disease

Medical research on tropical diseases was seriously disrupted when a "flash flood" drowned more than 200 experimental animals, including monkeys, dogs, cats, rats and mice, at the National Institute of Health near Bethesda, Md. Dr. R. E. Dyer, director of the institute, reported a loss in equipment and property of between $75,000 and $100,000. This, he said, was "nothing compared to the loss of strains of disease kept alive and under study in those animals. Some of them were flown here from China." Dr. Dyer said that records of much of the work were also lost. The disease under study is schistosomiasis, a tropical disease which attacks the liver. It was encountered by troops in the Southwest Pacific, infecting whole areas including the Philippines, the China Coast and Japan. The institute will have to send for more animals and start this special research all over again. The most serious loss is one of time.

U. S. War Casualties Total 1,061,648

The War Department reveals that war casualties for the week ended July 29 were 2,806, making a total of 1,061,648 since December 1941. Army losses are 197,676 killed, 570,766 wounded with 351,317 returned to duty, 34,734 missing and 117,741 prisoners of war, with 95,709 exchanged or returned to military control, making a total of 920,917. Navy losses are: Navy, 31,498 killed, 23,054 wounded, 10,547 missing, 2,038 prisoners, total 67,137; Marines, 19,385 killed, 50,465 wounded, 909 missing, 1,719 prisoners, total 72,478; Coast Guard, 808 killed, 213 wounded and 95 missing, total 1,116.

Civilians Clamor for Supplies of DDT

Since the revelation in the press that DDT, the magic insect killer, can be easily produced from nonpriority materials, drug stores throughout the country have been deluged with civilian requests for supplies. Already newspapers have printed news and feature stories describing in detail the formula and method of producing DDT. Official authority is awaited before large scale production for civilian use will be launched on a nation-wide scale.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Medical School Opens.—The Medical College of Alabama, Birmingham, opened officially June 4 with instruction of a junior class. On October 8 the School of Basic Medical Sciences on the University campus, where the first and second years are given, established in 1920, and its faculty will be absorbed into the new Medical College of Alabama. The School of Basic Sciences, direct successor in 1920 of the Medical College of Alabama at Mobile, organized in 1859, ceases to exist in October. The new Medical College of Alabama was established by action of the 1943 state legislature as a division of the University of Alabama. It was located in Birmingham in 1944 by vote of a special governor's commission. In 1945 it assumed title to Jefferson Hospital, Hillman Hospital, outpatient department, nurses home and all other city and county property of Jefferson County. In addition, the county and city gave to the university one block of property directly west, one half of which will be the site of a new health department building supported by state, county and city and to be affiliated with the Medical College of Alabama. Also two other blocks of adjacent property have been acquired by purchase by the university to serve as sites for other hospitals such as the Children's Hospital, the Crippled Children's Clinic and the Negro hospital, thus creating a four block medical center. In a fifth block south the university has purchased and remodeled apartment houses to provide living quarters for faculty and students. Under a ninety-nine year contract between the university and the county of Jefferson the Medical College of Alabama assumes responsibility for care of all indigent patients of county and city, maintenance of which is paid to the university on a per diem basis by the county. The 1943 appropriation included one million dollars for the building and equipment of a new medical school, which will be erected as early as possible after the war and connected under one roof with the new Jefferson Hospital. Under its contract the medical college receives authority for the appointment of the entire staff, medical and otherwise, of the combined hospitals.

CALIFORNIA

Position Available as Chief of Tuberculosis.—The California State Personnel Board is requesting applications to fill the position as chief of the state bureau of tuberculosis. Applications must be filed by August 30, and an examination will be held September 13. California residence has been waived. Candidates who are successful in the examination must obtain a license to practice medicine in California before they will be considered eligible for appointment. Education must include graduation from an approved medical school, completion of one year internship in a recognized hospital and completion of one year's graduate course in a recognized school of public health as well as three years' experience in the practice of medicine, including one year of full time experience as resident or associate physician in a tuberculosis sanatorium or hospital with a capacity of at least 50 beds. The salary will be $480 a month. Additional information may be obtained from the California State Personnel Board, 1015 L Street, Sacramento 14.

LOUISIANA

Dr. Brown Resigns as Director of Tuberculosis Control.—Dr. Reuben Alec Brown, New Orleans, has resigned as director of the division of tuberculosis control of the Louisiana State Board of Health. Newspapers reported that Dr. Brown will enter private practice in Houston, Texas.

Veterans' Psychiatric Service.—A veterans' psychiatric service has been established at the Veterans' Information Center, New Orleans, under the sponsorship of the Louisiana Society for Mental Health. The service will be available for the benefit of mentally disturbed veterans who cannot afford the cost of the services of a private psychiatrist. Dr. Milton E. Kirkpatrick, New Orleans, is clinical director with Dr. Walker Thompson, New Orleans, and Major H. Halbert Leet, M. C., assisting him.

NEW YORK

Provisions for Mental Care.—Plans for a $120,000,000 mental hospital construction program have been filed with the state postwar planning commission by Dr. Frederick MacCurdy, New York City, commissioner of mental hygiene, in anticipation of a large increase in the number of postwar patients, according to the New York *Times*. The commission on July 20 had approved $45,000,000 of these proposals, and early approval is expected for the others. The patient population of the state hospitals increased from 38,294 in 1920 to 83,053 in 1942. There were 82,108 under care on June 1. The recent decline is ascribed to the fact that more than 1,000,000 residents of the state are in military service and many persons who obtained employment during the war might have become patients had they remained idle.

Cornell Adopts Compulsory Physical Training Program.—On July 21 Cornell University, Ithaca, announced the adoption of a permanent compulsory physical education training program "designed to make such training enjoyable rather than a chore and emphasizing games and particularly carry-over sports beneficial to health after graduation." The program, evolved after study of three years' experience in conditioning army and navy trainees, was recommended as a requirement for all first and second year civilian men by the department of physical education and athletics. Effective with the opening of the current term the program, which normally will affect 3,000 underclassmen, is tied in with a cooperative venture of the university's medical department to provide corrective exercises. Freshmen and sophomores will be required to devote three hours weekly to the program.

New York City

Tuberculosis Admission Bureau Has New Offices.—The Tuberculosis Admission Bureau of the New York City Department of Hospitals, formerly located at 125 Worth Street, now has its offices at 535 East Eightieth Street. Application cards should be sent to the new address. All tuberculosis applications of the greater city of New York clear through the bureau.

Personal.—The degree of doctor of science was conferred on Dr. Margaret Barclay Wilson, Washington, D. C., professor emeritus of physiology and hygiene, at the recent commencement of Hunter College.——Dr. Trigant Burrow was given a Jubilee diploma by Fordham University during its recent commencement. The diploma is conferred on those who have been graduated fifty years from Fordham.

Ledyard Fellowship Available.—The Society of the New York Hospital announces that the Lewis Cass Ledyard Jr. Fellowship is now available. Applications should be addressed before November 15 to the committee of the Lewis Cass Ledyard Jr. Fellowship, Society of the New York Hospital, 525 East 68th Street, New York 21. The fellowship was established in 1939 by Mrs. Ruth E. Ledyard in memory of her late husband, Lewis Cass Ledyard Jr., who was a governor of the New York Hospital. The income, amounting to approximately $4,000 annually, will be awarded to an investigator in the fields of medicine and surgery or in any closely related field. Of this amount $3,000 will be applied as a stipend and approximately $1,000 for supplies or expenses of the research. In making the award, preference will be given to younger applicants who are graduates in medicine and who have demonstrated fitness to carry on original research of high order.

Restrict Sale of Penicillin and Other Antibiotic Drugs.—On July 24 the New York City Board of Health added a new section to the sanitary code restricting the sale of preparations containing penicillin or other antibiotic drugs to persons presenting a written prescription of a physician, dentist, podiatrist or veterinarian except in the cases of preparations which the board of health at some future date may specifically exempt from the provisions of the section. The new ruling became effective on August 1. In announcing the change Dr. Ernest L. Stebbins, health commissioner, gave three principal reasons for the board's action: Undertreatment may alleviate the symptoms of the illness without curing the disease, which in turn may continue to be communicable to other persons and to produce damage to the infected person; "there is also accumulating evidence of possible importance of the development of penicillin fast strains in persons who are inadequately treated," and, finally, these antibiotic drugs have been recently developed and there has not been sufficient time to determine the possible toxic reactions.

Orthopedic Hospital Merges with Columbia-Presbyterian Center.—The New York Orthopaedic Dispensary and Hospital and the Presbyterian Hospital at the Columbia-Presbyterian Medical Center were consolidated on July 23. The new corporation will be known as the Presbyterian Hospital in the City of New York. The orthopedic hospital will remain at its present site, 420 East 59th Street, until the fifth floor of the Presbyterian Hospital at 622 West 168th Street, part of the medical center, has been cleared of 70 student nurses housed there temporarily. The facilities of the orthopedic hospital eventually will be transferred completely and the building will be sold, the New York *Times* stated. The 70 student nurses will live in two additions to Maxwell House, now being built as part of the medical center's eight million to nine million dollar expansion program, which, it is estimated, will take about two and one-half years to complete. The orthopedic hospital erected its present quarters in 1916, with additions in 1925 and 1931 providing its present capacity of 145 beds in private rooms and wards. The Columbia-Presbyterian Medical Center currently combines services and facilities of the Presbyterian Hospital, Sloane Hospital for Women, Vanderbilt Clinic, Babies Hospital, Neurological Institute, Harkness Pavilion, Institute of Ophthalmology, J. Bentley Squier Urological Clinic, School of Nursing and the teaching facilities of the College of Physicians and Surgeons of Columbia University. Announcement was made also that a new 75 bed convalescent hospital for orthopedic patients would be built on property in King Street, Port Chester, N. Y., belonging to the orthopedic hospital. The Mary Harkness Home for Convalescent Care is on the 80 acre tract in Port Chester.

PENNSYLVANIA

Medical Club Observes Twenty-Fifth Anniversary.—The Bethlehem Medical Club celebrated its twenty-fifth anniversary in Bethlehem on June 7. Dr. Arno R. Zack, president, was toastmaster. Among the speakers were Dr. William L. Estes Jr., first president of the club, who recalled the initial steps taken by the Bethlehem physicians to organize a club in 1910 to "eliminate professional jealousy and to promote good fellowship."

Philadelphia

New Professor of Pathology.—Dr. Mollie A. Geiss has been appointed professor of pathology at the Woman's Medical College of Pennsylvania to succeed Dr. Helen Ingleby, who resigned in June to accept the position of pathologist at the Jewish Hospital (THE JOURNAL, July 7, p. 743). Dr. Geiss has been on the faculty of the college since 1923 and associate professor of pathology since 1932.

Temple Commencement Activities.—On June 21, during the commencement exercises of the Temple University School of Medicine, the degree of doctor of medicine was conferred on 127 young men and women coming from twenty different states, also Puerto Rico and the Hawaiian Islands. Eighty of the graduates were commissioned first lieutenants in the medical corps of the Army of the United States and 32 as lieutenants, junior grade, in the U. S. Naval Reserve. The commencement address was delivered by Charles F. Kettering, D.Sc., vice president and head of the research department of General Motors. Robert Silvercruys, Belgian ambassador to the United States, also delivered an address. Honorary degrees were conferred on both of these speakers. Eight physicians completed three years of postgraduate work and were awarded the degree of master of science in the specialty studied. Henning W. Prentis Jr., president of the Armstrong Cork Company, Lancaster, Pa., gave the principal address at the 121st annual commencement of Jefferson Medical College of Philadelphia, June 22. His subject was "The R's of Professional Education." He was given the honorary degree of doctor of laws. The present graduating class of 152 members brings the total number of graduates up to 17,507 during the 121 years of existence. The members of the graduating class were registered from twenty-one different states and two insular possessions. Ninety-five members of the graduating class received first lieutenant commissions in the medical corps, Army of the United States. Four members received first lieutenant, medical reserve corps, commissions. Presentation of commissions was by Lieut. Col. Frederick Hubbell Mills, M. C. These students received commissions after completing the requirements of the Army Specialized Training Program. Forty-one members of the graduating class received lieutenant, junior grade, commissions in the U. S. Naval Reserve. The commissions were presented by Capt. Lemuel M. Stevens, U. S. Navy, retired. Nineteen members of this group went on active duty as U. S. Naval interns. The presentation by the graduating class of 1945 of a portrait of Dr. Edward L. Bauer, professor of diseases of the child, was reported in THE JOURNAL, June 9, page 454.

GENERAL

Kansas Accident Report.—The 1945 edition of the "Kansas Accidental Death Report," which has been compiled annually for a little more than a decade, established trends and patterns in the occurrence of accidents. The state of Kansas, being industrial, agricultural, urban and rural, furnishes all kinds of situations in which accidents can occur.

Lawrence Linck Named Executive Director of Crippled Children Society.—Lawrence J. Linck, Chicago, has resigned as director of the Illinois division of services for crippled children to become executive director of the National Society for Crippled Children. Simultaneous with this report was one announcing the removal of the executive offices of the society from Elyria, Ohio, to Chicago. Mr. Linck will take over his new work September 1, at which time the new quarters are expected to be opened.

Research Fund Named for Sir Alexander Fleming.—The University of Pennsylvania on July 25 was selected to administer an $80,000 research fund established by American manufacturers of penicillin for Sir Alexander Fleming, discoverer of the drug. According to the New York *Times* the selection was a tribute to the role played in the development of the drug by Dr. Alfred N. Richards, vice president of the university in charge of medical affairs, who is credited with starting the program of producing the drug commercially. Under the terms of the trust, Sir Alexander has the widest latitude in administration of the money for scientific purposes. The results of the research will be free to any one. The work will be carried on by Sir Alexander at St. Mary's Hospital Medical School, University of London.

Meetings Canceled.—The council of the American Pharmaceutical Association has voted to postpone indefinitely the meeting of the council originally scheduled to be held in Chicago in September.——The executive council of the Association of Military Surgeons of the United States has voted to cancel the annual meeting, which was to have been held in Detroit October 24-27. The council further voted to retain in office the present officers of the association and to hold the 1946 meeting in Detroit.——The convention of the Aero Medical Association of the United States scheduled for September 24-26 at the Palmer House, Chicago, has been postponed.——The fifth International Assembly of the International College of Surgeons, which was announced for September 10-12 in Lima, Peru, has been postponed. The assembly will be held as soon as travel facilities become available. Dr. Max Thorek, 850 West Irving Park Road, Chicago 13, is international general secretary of the International College of Surgeons.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended July 28 have been received from the division of public health methods, U. S. Public Health Service, as follows:

Advisory Council for Insurance Research Fund.—An advisory council of eight members has been appointed for the life insurance medical research fund including the following:

Dr. Francis G. Blake, dean, Yale University School of Medicine, New Haven, Conn.

Dr. Ernest W. Goodpasture, dean, Vanderbilt University School of Medicine, Nashville, Tenn.

Albert Baird Hastings, Ph.D., Hamilton Kuhn professor of biochemistry, Harvard Medical School, Boston.

Dr. Eugene M. Landis, George Higginson professor of physiology, Harvard Medical School.

Dr. Robert F. Loeb, professor of medicine, Columbia University College of Physicians and Surgeons, New York.

Dr. Cyril N. H. Long, Sterling professor of physiologic chemistry, Yale University School of Medicine.

Dr. Seeley G. Mudd, professor of experimental medicine, University of Southern California School of Medicine, Los Angeles.

Dr. Cecil J. Watson, professor of medicine, University of Minnesota Medical School, Minneapolis.

The creation of the research fund was sponsored by the American Life Convention and the Life Insurance Association of America (THE JOURNAL, June 23, p. 606). A newly appointed council was nominated by a committee of four physicians including Drs. Alan Gregg, director of medical sciences, Rockefeller Foundation, New York; Alfred N. Richards, vice president in charge of medical affairs, University of Pennsylvania School of Medicine, Philadelphia; Lewis H. Weed, director, school of medicine, Johns Hopkins University, Baltimore, and Dr. Blake.

CANADA

National Immunization Week.—September 30-October 6 has been designated National Immunization Week, according to the Health League of Canada, which is sponsoring the observance in cooperation with health departments. The week is devoted to intensifying efforts to promote immunization against diphtheria, smallpox, whooping cough and scarlet fever.

Annual Meeting of Health League.—The twenty-sixth annual meeting of the Health League of Canada, formerly known as the Canadian Social Hygiene Council, will be held at the King Edward Hotel, Toronto, September 26-28. The theme of the meeting will be disease prevention, with separate sessions to discuss immunization, industrial health, nutrition, pasteurization and venereal diseases.

Degree Course in Physical Education.—McGill University, Montreal, has established a degree course in physical education, the first class to start in September. The course will be of four years' duration following junior matriculation or three years following senior matriculation or its equivalent. Open to both men and women students, it will lead to a degree of bachelor of science in physical education. The curriculum will include courses in English, physics, chemistry, zoology, anatomy, physiology, psychology, sociology, education, bacteriology, organization and administration, history, development and present day requirements in mental health, preventive medicine, nutrition and the technical application of physical medicine. Progressively arranged throughout the four years will be the technical and professional material involving basic technics in neuromuscular activity, principles of physical education, analysis and practice of activity, methods and analysis of teaching, curriculum content and planning, and practice teaching. The school of physical education at McGill, said to be the oldest of its kind in Canada, was established in 1912. The new program will be the first degree course offered by the school, which is an integral part of the faculty of medicine.

FOREIGN

Pasteur Institute Receives Grant for Penicillin.—The French government has made a grant of 10,000,000 francs to the Pasteur Institute, Paris, to enable it to develop research into the preparation of penicillin, it is reported.

Memorial Service for Dr. Thierry de Martel.—Impressive religious services were held June 14 at Neuilly-sur-Seine in memory of Dr. Thierry de Martel, formerly chief surgeon at the American Hospital of Paris. Dr. de Martel had reached his sixty-fifth birthday in June 1940, when the Germans entered Paris. On the night of June 13-14 he took his own life, thus obviating practically certain imprisonment and compulsion to work for the Germans against his own countrymen.

Personal.—Major Greenwood, D.Sc., has retired as professor of epidemiology and vital statistics at the University of London School of Hygiene. Because of a change in the distribution of teaching and the steady increase in the volume of research work and teaching within the field of medical statistics, the title of the chair has been altered to that of medical statistics and A. Bradford Hill, since 1933 leader in medical statistics in the university, has been appointed to succeed Dr. Greenwood, who has been given the title of professor emeritus in epidemiology and vital statistics.

Government Services

Care of Children in Liberated Countries

Support of the National Commission on Children in Wartime to the policies of the United Nations Relief and Rehabilitation Administration in the care of children in the liberated countries was expressed in a statement prepared by a committee of the commission and released recently. In view of the frightful things that have happened and are happening to children and the need for prompt action in identifying children and restoring them wherever possible to their families, the statement urged that the policies be developed immediately by the highest army authorities and UNRRA in regard to the services to be rendered by the latter in dealing with displaced children in territories under military control. In addition to expressing concern as to the fate of thousands of homeless children, the committee in its conference with Herbert Lehman, director general of the UNRRA, June 12, stressed the need for arousing the people of this country to the fact that children in Europe are starving or near starvation because they do not have the protective foods, particularly meat and milk, to which this country must be looked as the main source of supply. The committee included Mr. Leonard W. Mayo, Cleveland, head of the committee of the National Commission on Children in Wartime and president of the Child Welfare League of America; Katharine F. Lenroot, Washington, D. C., chief of the Children's Bureau, U. S. Department of Labor; J. Milton Patterson, Chicago, American Public Welfare Association; Maxwell Hahn, New York, Field Foundation, and Dr. Leona Baumgartner, New York, American Public Health Association.

Meeting of the National Advisory Health Council

At a meeting of the National Advisory Health Council at the headquarters of the U. S. Public Health Service, Bethesda, Md., June 19-20, to discuss current and future activities of the several bureaus of the public health service, recommendations were made that:

A committee of the council be appointed to act with designated officers of the service in the development of a program of clinical research in the Public Health Service.

The Public Health Service strengthen its control of the interstate spread of disease through consultant services to public health laboratories and through maintenance of a $1,000,000 emergency fund to be used in epidemics and disasters.

The Public Health Service undertake demonstrations in selected communities of generalized public health nursing programs, including bedside care.

The Public Health Service establish a training program for its own personnel, which would include orientation, work experience, observation, in-service training, and opportunities for state and local personnel to participate.

The program of grants-in-aid and technical services to the states in the field of industrial hygiene be expanded.

The Public Health Service seek appropriations for grants-in-aid for general research to be allotted to qualified institutions and individuals.

When the federal government undertakes grant-in-aid programs related to public health and sanitation, the Public Health Service be empowered to conduct investigations for determination of the nature and extent of the problems involved and to approve the allocation of funds, functional effectiveness and placement of plants, installations and constructions required of such programs.

The council also recommended the approval of a grant in aid of $92,000 to the University of Utah for research on muscular dystrophy, which, according to an announcement, is the first grant-in-aid for general research projects to be made under the provisions of the public health service act of 1944 (P. L. 410). This is the law that authorized the council, which had been serving in only an advisory capacity, to have the legal responsibility to:

. . . advise, consult with and make recommendations to the Surgeon General on matters relating to health activities and functions of the service; and to serve in other capacities as requested.

Recommend research projects for grants-in-aid in scientific fields other than cancer research, and recommend other procedures for the advancement of scientific research.

Recommend the adoption of regulations by the service with respect to interstate quarantine for the prevention of communicable diseases, including regulations for the apprehension, examination and detention of persons who are spreading disease.

The council will hold regular meetings twice a year, special meetings to be called as needed. Members of the council are to serve as chairmen of special committees dealing with specific subjects.

The Slowness of Medical Demobilization: Government Criticized by the British Medical Association

For some reason which the government will not explain, demobilization of the fighting services is very slow. In the case of medical service great dissatisfaction has been expressed by the British Medical Association. At a meeting held at the headquarters of the association Dr. Guy Dain, chairman of the council of the association, who presided, explained that the association could not find out which groups of doctors were likely to be demobilized. The position with regard to the civilian population was very difficult. Doctors were very badly needed and the profession had been driven to great lengths to meet that need. Doctors were not able to get back to their practices, and the association was getting many letters of protest from men who were serving but so far had not been able to get any satisfaction. The profession had carried on at home with the ratio of 1 doctor to 3,000 civilians in urban areas and 1 to 2,400 in rural areas, whereas in the fighting forces there was on an average 1 doctor to every 350 men.

Dr. Charles Hill, secretary of the British Medical Association, said that unless at least 5,000 doctors were released for work among the civilian population next winter a grave situation might arise in the event of an epidemic. In a letter to the *Times* he pointed out that approximately one third of the doctors in the country are serving with the forces. The Central Medical War Committee of the association suggested the continuance of recruitment after the end of the German war in order to facilitate demobilization, and the government accepted this. Although recruitment is proceeding, the committee has not been informed of the quota of doctors to be supplied for 1945. Accordingly it does not know the extent to which, if at all, the recruitment will find expression in accelerated release. In spite of repeated requests the committee has not been informed of any time table for demobilization apart from certain groups. Until a long term program is announced, the intense dissatisfaction which now exists will continue. The government has decided, against the protest of the committee, not to continue to recruit medical women. This decision will hamper recruitment and so delay demobilization.

Great Success of Medical Measures in the Burma Campaign

The campaign in the malarious jungles of Burma has been a serious problem for the army medical service. In the early days sickness, largely due to malaria, was as high as 300 per cent annually. Whole units were incapacitated at a time. But, thanks to new methods vigorously applied, the rate has been reduced to only 4 per cent. Only two years ago 70 per cent of all army sickness was due to malaria. Last year this rate fell to 36 per cent and in the first four months of the present year to 27 per cent. The malaria rate has been reduced to 17 per cent of what it was at the corresponding time last year.

This astonishing improvement is due to the thoroughness of the antimalaria measures. Close behind the advancing troops both the ground and the air forces send out men to survey malarious tracts of country, select camp sites and plan the work of the malaria control units. Camp areas are sprayed with the insecticide DDT. Trickling jungle streams, the seepage of swamps, are canalized or attacked with DDT, for these are the breeding places of Anopheles minimus, the cause of the high malarial rate in Assam. Brackish swamps and lagoons near the sea are the breeding places of another variety of mosquito, Anopheles sundaicus, which infects the Arakan coast. These places are oiled or drained by deep channels into tidal streams. Last year three new measures were adopted: the administration of mepacrine to the troops; the introduction of DDT, which is not only sprayed in tents and buildings but over malarious tracts of country by low flying aircraft, and the use by forward troops of fish net veils soaked in "scat," the American repellent dimethyl phthalate. Under military discipline every soldier takes daily a tablet of mepacrine and wears long trousers and buttoned sleeves to reduce the risk of mosquito bites.

Another advance is the sending of supplies by air. When the medical officer commanding an advanced unit requires anything, he radios to the base and within a few hours is supplied by parachute. Even blankets and stretchers are dropped by air, and surplus supplies are returned with the wounded. Under this system the amount of stock that need be kept on hand by the unit is much reduced and the advantage is gained that the unit can travel light.

Great Development of Rehabilitation Treatment

As reported previously in THE JOURNAL, rehabilitation has received much increased attention as a result of war injuries. The present position is summarized in an address by the minister of health, Mr. Willink, to representatives of the British Council for Rehabilitation. In the Emergency Medical Service (established during the war mainly for the treatment of civilian casualties due to German air raids) more than 11,000 patients are taking daily courses of remedial exercises in their beds. In addition 20,000 are attending hospitals for special exercises and remedial games. Of these 31,000 persons receiving rehabilitation, 15,000 are taking part in some form of occupational therapy. Since the Ministry of Health made a special survey with the object of extending these facilities, the number of hospitals providing rehabilitation for their patients has increased from 150 to 300. The great majority of the sick and wounded from the fighting services are receiving their medical rehabilitation in the hospitals of the Emergency Medical Service. More than 250 doctors have been given special training, and for hospitals handicapped by lack of accommodation the ministry has provided thirty-four prefabricated buildings. Conferences have been held throughout the country for leaders of industry, personnel managers, welfare officers and industrial medical officers, to explain the whole process of rehabilitation and the part which industry has to play in the resettlement of patients.

The minister of health added that there is no intention to relax this campaign. Wartime progress must not be lost in peacetime. The success of rehabilitation methods would lead to increased demand which hospitals throughout the country were already getting ready to meet. The Ministry of Health would retain its Rehabilitation Department and was fully prepared to continue to encourage and assist the development of these facilities as an integral part of the health services. The British Council for Rehabilitation could perform a most useful work in bringing together the medical and industrial points of view.

Science Under the Nazis in Denmark and Norway

Prof. A. V. Hill, secretary of the Royal Society, has returned from a visit to Norway and Denmark to present to the academies of the two countries the greetings of the society and copies of all that it has published since 1940. He reports that science has not suffered under the Nazis in Denmark as badly as in most countries. Until the autumn of 1943 they were on their best behavior, but then the Gestapo became active and students ceased to attend the colleges. Professor Rehberg, zoologist, was brutally mishandled for lack of cooperation and, with many other scientists, was imprisoned. The chief scientific need is books and journals and English textbooks for students. But so

quickly have the Danes reestablished themselves that they are contemplating an expedition for marine biologic investigation off the west coast of Africa.

Norway has suffered more than Denmark. The president of the academy, Professor Bull, was three years in a concentration camp. The scientific laboratories were stripped of equipment, and scientific work suffered and the Norwegians have great difficulties in getting their courses started again. Medicine attained a high standard in Norway before the war. The Danes are taking a large number of Norwegian medical students, and Norway is anxious that some of her best postgraduate students should study over there. In both countries the most friendly relations exist with Britain, and English bids fair to become a second language. Both desire to use our books and scientific instruments in place of those formerly imported from Germany.

Visit of Brazilian Plastic Surgeon

Dr. David Adler, consulting plastic surgeon to the Air Force Hospital, Rio de Janeiro, is in this country on a six months visit, arranged by the British council. During his visit he will work with Sir Harold Gillies, the leading British plastic surgeon.

RIO DE JANEIRO, June 30, 1945.

Penicillin in the Treatment of Frambesia

Dr. A. Marques da Cunha and Dr. A. Area Leão, at the Oswaldo Cruz Institute, have been conducting extensive studies and experimentation for several months on the therapeutic effects of penicillin in some important tropical diseases. One series of studies relates to frambesia, or yaws, a disease in which the extensive skin lesions and the abundance of treponemes permit objective evaluation of the results of treatment. The first experiments were performed with barium penicillin solution prepared at the institute. Seven patients treated with penicillin alone were clinically and microscopically cured in twelve to forty-four days. The penicillin was injected at intervals of four to six hours, 200 Oxford units being used each time. The total dose per patient varied from 9,600 to 52,000 units. In spite of the frequency and the number of injections, no toxic effects were noted. The patients were maintained during six months under weekly immunologic control.

The second group of experiments involved 5 patients treated with dried sodium penicillin of American make. The same dose of 200 units was used, adding up a total which varied from 24,000 to 54,000 units for each patient. The healing of the skin lesions and the disappearance of the subjective symptoms were obtained as in the first series of patients. The immunologic cure in all the cases of the two series did not immediately accompany the clinical cure: it took a few months to develop negative Wassermann reactions in all the 12 cases.

Revision of the Pan American Sanitary Code

The tenth Pan American Conference of National Directors of Health, held in Washington in 1944, decided to amend the present Pan American Sanitary Code, adopted twenty-five years ago by the nations of the Western Hemisphere. In fact, the present code in many points is not in accordance with the advancements of the medical sciences and is quite inadequate in some others to meet the conditions created by the rapid development of air transportation. Furthermore, some new subjects, in addition to the control of transmissible diseases, need to be included in the code as the sanitary activity has been expanded to comprehend a few modern problems. According to that decision Dr. Hugh S. Cumming, director of the Pan American Sanitary Bureau, appointed Dr. J. de Barros Barreto, director general of the National Department of Health of Brazil, Dr. Solon Nunez, secretary general of health of Costa Rica, Dr. Rafael Schiaffino, director of the department of health of Uruguay, and Dr. Garza Brito, professor at the School of Public Health of Mexico, to prepare a draft of a new code, to be presented to the twelfth Pan American Sanitary Conference, to be held in Caracas, Venezuela, in 1946. The committee is now working at Rio de Janeiro under the chairmanship of Dr. Barros Barreto.

Experimental Infection with Leishmaniasis Americana

The experimental infection with leishmaniasis americana is a subject not yet sufficiently studied. Dr. A. Marques da Cunha of the Oswaldo Cruz Institute has just published an interesting paper on an experimental study in which he succeeded in infecting the rhesus monkey with the agent of the disease (Leishmania brasiliensis), causing the production of mucous lesions similar to the ones described in man. The causative agent of leishmaniasis americana should not be confused with the agent of American kala-azar, or visceral leishmaniasis, i. e. Leishmania chagasi. The inoculations were made intradermally about the superciliary arches or into the skin of the nose. The incubation period ranged from one to two months. The course of the infection varied according to whether the lesions were limited to the skin or also invaded the mucous membranes. In the former the infection lasted from three to eight months and always terminated in spontaneous cure. When the lesions were also present in the mucous membranes they tended to persist and evolve, while the skin lesions observed in the same animal became regressive and tended to healing and cure. Dogs also were inoculated, with positive results, the incubation period being about two months and the skin lesions tending always to terminate by cure. Other tropical monkey-like animals, such as Dasyprocta agouti, when inoculated never showed the infection. One rhesus monkey which recovered from an infection by L. brasiliensis could not be infected when inoculated with another strain of the same parasite. The extent of the lesions of the mucous membranes in experimental infections of rhesus monkeys by Leishmania brasiliensis, a fact not yet observed with Leishmania tropica, constitutes a strong argument in favor of the independence of the two species.

Marriages

DONALD EWING TINKESS, Greenwich, Conn., to Mrs. Clyde Manson Trotter of Chattanooga, Tenn., in Columbia, S. C., June 16.

ANIBAL ROBERTO VALLE, Charlottesville, Va., to Miss Rose Mary Keupper of Gillespie, Ill., in Washington, D. C., June 25.

RICHARD PHILLIPS BELL, Staunton, Va., to Lieut. Hilda Steele Franklin, A. N. C., of Fieldale, May 26.

MALCOLM C. TODD, Lawrenceville., Ill., to Miss Ruth Holle Schlake of Chicago in London, England, June 12.

FRANCIS MICHAEL SMITH JR., Vicksburg, Miss., to Miss Betty Thibaut of Donaldsonville, La., in June.

JAMES LEONIDAS CAMP III, Franklin, Va., to Miss Jane Elizabeth Geuting in Philadelphia in May.

FREDERICK WILLIAM WOOD JR. to Miss Patricia M. Wright, both of Garden City, N. Y., June 15.

ROBERT LOFTUS BRERETON, Kirkwood, Mo., to Miss Ann Van Dyke of St. Louis, June 23.

WILLIAM PARKS BLACKMON, Atlanta, to Miss Dorothy Mae Ware of Mayo, Fla., June 21.

GUSTAV JULIUS BECK to Miss Rita Levitiss, both of Gloversville, N. Y., May 12.

ORVILLE W. WINTERS to Miss Ruth Mae Weber, both of Cincinnati, July 28.

GEORGE C. TRUMAN, Mesa, Ariz., to Lieut. Dorothy Hinson recently.

LYNN McIVER to Miss Elva Bryan, both of Sanford, N. C., June 5.

Deaths

James Bertram Overton, Talmage, Calif.; Washington University School of Medicine, St. Louis, 1931; began active duty as a captain in the medical corps, Army of the United States, on Nov. 13, 1942; assigned to chief neuropsychiatric service at Stockton; transferred to several other fields, serving also at Denver; relieved from active duty because of physical disqualification on June 25, 1944, honorably discharged Dec. 21, 1944; at one time associated with the U. S. Public Health Service Reserve; interned at the State of Wisconsin General Hospital in Madison and Johns Hopkins Hospital in Baltimore; interned at the Evansville (Ind.) State Hospital, where he also served a residency, served a residency at the Arizona State Hospital, Phoenix, New Mexico State Hospital, Las Vegas, Weston State Hospital, Weston, W. Va., Utah State Hospital, Provo, and at the Mendocino State Hospital, where he had been a member of the regular staff; died in Ukiah March 28, aged 40, of cerebral hemorrhage.

William Hamilton Jefferys, Haverford, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; formerly a medical missionary in China, where he served for many years as professor of surgery, lecturer on tropical diseases and dean at St. John's University and associated with the Blind in Philadelphia for many years; served as executive superintendent of the Home for Consumptives in Chestnut Hill; retired superintendent of the Philadelphia Protestant Episcopal City Mission; formerly editor of the *China Medical Journal*; author of several books and articles on Christian mysticism; died in Philadelphia May 14, aged 73.

Orley Mason Vaughan Jr., Covert, Mich.; Northwestern University Medical School, Chicago, 1911; chairman of the board of the Tri-County Telephone Company, which he organized in 1924, serving as its president in 1940; instrumental in organizing the Michigan Independent Telephone Association; a director of the United States Independent Telephone Association; past president of the board of education of Covert; instrumental in creating the Covert Consolidated school district, of which he was also president; served as chairman of the county poor commission; died in Fort Lauderdale, Fla., April 23, aged 60, of cerebral hemorrhage.

John Mark O'Farrell, Houston, Texas; Memphis (Tenn.) Hospital Medical College, 1891; member of the American Medical Association and of its House of Delegates in 1920; honorary member of the State Medical Association of Texas; past president of the South Texas Medical Association; served during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; a member of the first state board of health; served on the staffs of the Memorial, Methodist and St Luke's and St. Elizabeth's hospitals in Shanghai; fellow of the College of Physicians of Philadelphia; past president of the American Association of China, honorary fellow of the China Medical Society; chairman, instruction committee, and vice president of the Pennsylvania Institute for Instruction of Jefferson Davis hospitals; for many years surgeon for the Santa Fe Railroad; died May 23, aged 79.

Harvey Arbuckle, Boonton, N. J.; College of Physicians and Surgeons, Baltimore, 1904; died May 13, aged 71, of congestive heart disease and pernicious anemia.

LIEUT. ANTHONY GUS KERASOTES
(MC), U.S.N.R., 1912-1944

LIEUT. (JG) JOHN F. KINCAID JR.
(MC), U.S.N.R., 1917-1945

LIEUT. COMDR. DANIEL J. MCCARTHY
(MC), U.S.N.R., 1908-1945

KILLED IN ACTION

Anthony Gus Kerasotes, Springfield, Ill.; St. Louis University School of Medicine, 1940; member of the American Medical Association; interned at St. Mary's Group of Hospitals in St. Louis; entered the medical corps of the U. S. Naval Reserve as a lieutenant (jg) on Sept. 10, 1942; received training at Parris Island, N. C., and served as medical officer at Savannah, Ga., naval base; participated in the invasions of North Africa and Sicily and the landings in Italy, served on board the U. S. S. *Leary* when the vessel was torpedoed in the Atlantic area while engaged in an antisubmarine patrol; promoted to lieutenant; reported missing in action as of Dec. 24, 1943, presumptive date of death Dec. 25, 1944, aged 32.

John Franklin Kincaid Jr., Leesburg, Va.; Duke University School of Medicine, Durham, N. C., 1942; diplomate of the National Board of Medical Examiners; interned at the Johns Hopkins Hospital in Baltimore; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on July 10, 1943; died in the Asiatic area April 12, aged 27, of blast concussion.

Daniel Joseph McCarthy, Savannah, Ga.; St. Louis University School of Medicine, 1935; member of the American Medical Association; interned at St. Louis City Hospital; served as assistant resident surgeon at St. Joseph Hospital; entered the medical corps of the U. S. Naval Reserve as a lieutenant (jg) on Oct. 2, 1940; began active duty in the same grade on July 28, 1941, assigned to Charleston, S. C.; later promoted to lieutenant and lieutenant commander; died in the Pacific area February 22, aged 36, of fragment wound of the upper extremities.

Henry George Blanchard, Fairmont, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; member of the American Medical Association; died in the Community Hospital April 13, aged 76, of chronic myocarditis and arteriosclerosis.

Charles H. Burton, Iva, S. C.; University of Georgia School of Medicine, Augusta, 1903; formerly mayor of Iva; died May 2, aged 68, of coronary thrombosis.

George Harold Carpenter, Marion, Ohio; Toledo Medical College, 1912; died April 9, aged 61, of pneumonia.

Henry Clinton Cooney ✠ Princeton, Minn.; College of Physicians and Surgeons of Chicago, 1887; fellow of the American College of Surgeons; served as president of the Northern Minnesota Medical Association and the East Central Minnesota Medical Society; until March 1944 local health officer; for many years local surgeon for the Great Northern Railway; owner and medical director of the Northwestern Hospital; died April 1, aged 81, of cardiac decompensation.

Charles Aaron Hull, Omaha; Denver College of Medicine, 1893; formerly assistant professor of surgery at the University of Nebraska College of Medicine; fellow of the American College of Surgeons; at one time on the staff of the Immanuel Hospital; served during World War I; died May 8, aged 75, of bronchopneumonia and cerebral hemorrhage.

James Riley Kinney, Fort Valley, Ga.; Southern Medical College, Atlanta, 1889; at one time mayor of Fort Valley; died May 9, aged 81, of chronic myocarditis and arteriosclerosis.

Frederick Willer Meyer ✠ Capiz, P. I.; Yale University School of Medicine, New Haven, Conn., 1919; fellow of the American College of Surgeons; a member of the House of Delegates of the American Medical Association, 1937-1938; a missionary of the American Baptist Foreign Mission Society; director and chief surgeon, Emmanuel Hospital; died on the Island of Panay Dec. 20, 1943, aged 51, while in the custody of the Japanese.

Davis Strom Porter, Andrews, S. C.; Atlanta College of Physicians and Surgeons, 1910; served as mayor and councilman; for many years physician and surgeon for the Atlantic Coast Lumber Corporation and the Seaboard Railroad; died in a Florence hospital March 31, aged 62, of nephritis and cardiac decompensation.

Otto William Schwalb, Fort Lauderdale, Fla.; University of Georgia Medical Department, Augusta, 1928; member of the American Medical Association; served as secretary of the Georgia Medical Society; director of the Broward County Health Department; member of the tuberculosis board of Broward County; formerly city physician of Savannah, Ga.; died April 17, aged 42, of coronary thrombosis.

Capt. Aaron Emil Oswald
M. C., A. U. S., 1914-1945

Capt. Leroy William Yolton,
M. C., A. U. S., 1900-1945

Lieut. Charles W. Pfeiffer
M. C., A. U. S., 1918-1944

KILLED IN ACTION

Aaron Emil Oswald, Casper, Wyo.; College of Medical Evangelists, Los Angeles, 1941; interned at St. Luke's Hospital in Denver; served as assistant chief resident physician at Kern General Hospital in Bakersfield; commissioned a first lieutenant in the medical corps, Army of the United States, on May 27, 1942; later promoted to captain; bomber squadron flight surgeon; during the nearly two years that he was overseas he had been twice decorated for valor, the first for "meritorious achievement" while participating in aerial flights in the Southwest Pacific area from Jan. 5 to Oct. 3, 1944, and the second decoration, the Soldiers' Medal, was awarded to him in August 1944 for saving a gunner from burning plane wreckage; died February 24, aged 30, from a bomb-load explosion that followed his rescue of a pilot trapped in a burning plane on Morotai Island in the Pacific.

Leroy William Yolton ✠ Bloomington, Ill.; Rush Medical College, Chicago, 1931; interned at St. Luke's Hospital in Chicago, where he served a residency; began active duty as a captain in the medical corps, Army of the United States, on Sept. 3, 1942; killed in action in Luzon, P. I., February 3, aged 44.

Charles William Pfeiffer, Racine, Wis.; University of Chicago School of Medicine, 1942; interned at the Augustana Hospital in Chicago; at the age of 21 was commissioned a second lieutenant in the Field Artillery, since he was an R. O. T. C. member after graduating from Culver; on receiving his medical degree was transferred to the Medical Officers Reserve Corps with the rank of first lieutenant; began active duty on Dec. 30, 1943 as a first lieutenant in the medical corps, Army of the United States, and was assigned to the O'Reilly General Hospital in Springfield, Mo., for two months; transferred to Mason General Hospital in Brentwood, Long Island, for a three month course in neuropsychiatry; after a few months at Longview, Texas, went to Camp Atterbury, Ind., where he joined the 331st medical battalion of the 106th Infantry division; arrived in England about the middle of November 1944; wounded in the battle of Ardennes, Dec. 21, 1944; reported dead on Dec. 23, 1944, aged 26, while a prisoner of the German government.

Correspondence

SURGICAL-PATHOLOGIC COOPERATION IN LOWERING OPERATIVE INCIDENCE OF SO-CALLED CHRONIC APPENDICITIS

To the Editor:—The great discrepancy that exists between the clinical diagnosis of chronic appendicitis and many apparent nonpathologic appendixes subsequently reported by some pathologists as chronic appendicitis presents a serious and challenging problem to all clinicians and especially to surgeons.

In no other field of surgery is there tolerated so flagrant a violation of diagnostic and pathologic fundamentals. The growth of this pernicious practice is due to three errors: First, inadequate and hasty study by the clinician. All too frequently we find the first and easiest diagnosis to be chronic appendicitis, whereas the correct approach would be to proceed on the basis that this is the last possible diagnosis and should be arrived at only after all studies and adequate consultations have ruled out other diseases which may easily simulate chronic appendicitis. Only after this are we justified in subjecting the patient to surgery. The wisdom of the phrase "Error is always in haste" is often apparent as we review diagnostic errors. Failure to carry out adequate diagnostic study is the clinician's responsibility.

The second error is the lamentable trend shown by many pathologists to report slight alteration from the normal pattern as a diseased appendix for no other apparent reason than the fact that it was removed surgically. In the majority of cases this same pathologist, without knowing the operative history or the surgeon, could call these specimens normal appendixes. This is the pathologist's responsibility.

The third error is the indifference or inability of the clinician and pathologist to review the surgical specimen which is found to be normal. The clinician profits immensely by wholesome discussion of his problem, and an occasional admission of a diagnostic error will help to develop his future clinical judgment. This is demonstrated by the successful clinicopathologic conferences held today in many institutions. "From the errors of others a wise man corrects his own."

Although my own observations are limited to areas along the Eastern seaboard, the magnitude of this problem is well emphasized by the experience of the professor of medicine in one of our large Eastern medical colleges. After completing a transcontinental clinical trip he expressed alarm over the extraordinarily large number of appendectomies performed for chronic appendicitis through the entire country.

A pathologist in a distant community recently finished a study on a series of 335 appendixes removed for acute and chronic appendicitis. Of this group 72 per cent definitely showed gross and microscopic changes justifying the preoperative diagnosis. The remaining 28 per cent that did not show demonstrable disease was broken down for more critical analysis, using a code for each surgeon in order to maintain a critical attitude. The results showed beyond the slightest doubt that the better qualified surgeon removed infinitely fewer so-called chronic appendixes.

One institution has succeeded in reducing the rate of operative procedures for chronic appendicitis from 46 per cent to 10 per cent within the space of a few months by application of the aforementioned criteria for diagnosis; it would seem that this example might well be followed by many more hospitals.

EDWIN J. GRACE, M.D., Brooklyn.

NEOSTIGMINE METHYLSULFATE FOR PREECLAMPSIA

To the Editor:—The employment of neostigmine in the treatment of preeclampsia as suggested by Woodbury and his associates in THE JOURNAL, June 23, is based on principles underlying recent orientation on the etiology of the late toxemia of pregnancy (Hofbauer, J. I.: *West. J. Surg.* **49**:615 [Nov.] 1941; *Cincinnati J. Med.* **23**:107 [May] 1942; *Am. J. Surg.* **45**:361 [Sept.] 1944). The many theories advanced during past decades have failed to receive obstetric approval elucidating the true nature of the disorder.

While in the past the placenta was generally considered the chief characteristic of the pregnant state and, in toxemia, the principal factor responsible for the elaboration of "toxins," the new tenet inclines to the view that the pregnant state is essentially conditioned by the altered basic endocrine pattern. Notable among the hyperplastic changes occurring in the ductless glands during pregnancy are the phenomena in the adrenal cortex, the thyroid and the anterior hypophysis. In the present discussion the demonstration of increased secretion of the basophils during the last trimester of normal gestation and of cortical structures has first call in view of the clinical evidence that the adrenal cortex as well as the pituitary basophils may serve as factors in the genesis of hypertension (Rinehart, J. F.; Williams, O. O., and Cappeller, W. S.: Adenomatous Hyperplasia of the Adrenal Cortex Associated with Essential Hypertension, *Arch. Path.* **32**:169 [Aug.] 1941. Selye, Hans; Rowley, E. M., and Hall, C. E.: *Canad. M. A. J.* **49**:88 [Aug.] 1943). These factors, in conjunction with augmented reactivity of the arterioles to pitressin as the result of the presence during pregnancy in the blood of placental sex hormones in concentrations far above anything occurring in the nonpregnant state, serve as a basis for the appreciation of a delicately adjusted equilibrium between the opposing effects on the blood pressure of the endocrine factors and placental acetylcholine. A disturbance of this balance in toxemia was demonstrated by the reports of my associates of remarkably low acetylcholine values in 28 placentas and by the evidence adduced by Mukherjee of increased concentration in the blood of postpituitary principles in toxemia. These investigations have brought into clear relief the etiologic relationship between undue pitressin effects and the causation of toxemia. To the summation of the experimental, morphologic and chemical facts pointing in this direction, as recorded in previous communications, may be added the recent demonstration of the blood concentrating effect and of the phosphorus raising action of the pressor hormone by Stehle and Bourne (*J. Physiol.* **64**:229).

The cardinal aspects which enter into the rational therapy of preeclampsia entail primarily the preservation as far as possible of the functional integrity of the liver as the organ most concerned with the excretion and detoxication of pitressin and thyroxine. In view of my observations of the effects of neostigmine, which closely parallel the report of Woodbury, I hesitate to recommend this drug. There is, however, another consideration concerning the potentiation of naturally occurring placental acetylcholine by inhibiting cholinesterase. The most valuable sedatives in the treatment of eclampsia (morphine, barbiturates) strongly inhibit cholinesterase, as recently shown by the studies of E. A. Zeller (*Helv. chim. acta* **26**:1619, 1943) and F. Schütz (*J. Physiol.* **102**:259 [Dec. 31] 1943). Their empirical clinical use in eclampsia may thus be rationalized.

J. I. HOFBAUER, M.D., Cincinnati.

THE SUPPLY OF LABORATORY SERVICE

To the Editor:—In THE JOURNAL, June 16, page 539, Dr. Theodore Curphey criticized Montgomery County's method of supplying medical laboratory service to the public. His main objections were that: 1. If put into practice throughout the state and in other states, the system would "seriously jeopardize the healthy and natural development that laboratory medicine is now enjoying." 2. It would "limit the freedom of choice of the younger pathologist and would tend to force him into seeking state laboratory appointments." 3. It would "place at a serious economic disadvantage those private pathologists who work in proprietary hospitals or have laboratories of their own and who engage in private practice." 4. "These two things would be serious deterrents to the entry into the specialty of pathology by younger men." 5. The public's appreciation of pathologic services would be weakened because it is free. 6. "It might be harmful also to organized medicine in that . . . attempts might be made to offer the services of other medical specialists on the same basis to the community."

The first two of these objections are apparently based on a misapprehension of the facts. The Montgomery County Laboratory is not a state laboratory. It is entirely under county control. The expenses are paid jointly by the county and by the state. The intention of the state is, I believe, to encourage counties to supply laboratory service in those communities where it does not exist. Such communities are likely to be those whose population is too small to support the private practice of a pathologist and too distant from large centers to utilize existing facilities. By combining public health, hospital, medicolegal and outpatient work in one laboratory there may be enough to absorb the full time and interest of a pathologist, as in Montgomery County. It is desirable that most laboratory specimens be examined soon after collection, that the pathologist be familiar with local conditions and that he be available as a consultant. Furthermore, in many cases he needs information as to the clinical features. All this can be accomplished only if the laboratory is close to the community it serves.

While the Montgomery County type of laboratory is particularly suited to our community, this does not mean that it should be adopted in larger, more densely populated, areas or in places where satisfactory laboratory service is in existence. There is no danger that such a system will be "put into practice throughout the state and perhaps also in other states," nor does the New York State Department of Health propose to do so. It only provides aid to those communities which decide that they need it.

It will also be seen that objection 3 has no application to Montgomery County, for it was precisely the lack of private pathologists that incited the county to establish its laboratory. Indeed, the introduction of laboratory service where it is lacking creates additional positions for pathologists.

Objection 4 would be extremely serious if it should be corroborated. Before deciding what would deter younger men from entering the specialty of pathology, it would be desirable to ask the younger men that question. In my opinion there are at present two extremely serious and widespread deterrents to the specialty of pathology. The first is the low remuneration of pathologists in comparison to other physicians of equal training and degree of specialization. But this is at least as true of pathologists working in voluntary hospitals as of those employed in organizations such as the Montgomery County Laboratory. The second is the exclusion of pathologists from medical boards and generally from the direction of medical affairs in many hospitals. In Montgomery County the pathologist is a member of the staff of the two voluntary hospitals and has as much say in the government of the hospitals as the other physicians. The foregoing two factors being equal, I can see no reason for supposing that the type of administrative organization, whether hospital or county laboratory, would make the least difference to a young physician in deciding whether to enter pathology or another specialty.

Objection 5 deals with imponderables. As far as Montgomery County goes, my impression is that the public has shown at least as much appreciation of the free service as has been shown for paid services in other communities with which I am familiar.

Objection 6 can be judged only by the facts. In this county no such attempt has been made or, to my knowledge, even suggested. The county medical society was consulted and approved the laboratory plan before it was adopted.

Dr. Curphey concludes that a solution of the matter should be "motivated by a sincere desire to give an all inclusive modern laboratory service to communities, on a basis of individual community needs and not as is recommended in the Montgomery County Plan, as an overall free public service." All inclusive modern laboratory service on a basis of individual community needs is precisely what has been supplied in Montgomery County.

Finally, Montgomery County has made a contribution to pathologic service to the community which is worth pointing out. This is the recognition of autopsies as a vital public health service. In this county, autopsies are performed freely, not only, as in most places, on cases in which death has occurred in hospitals or medicolegal cases but on nonhospitalized cases as well. In addition to the public health value of this arrangement, it aids in research requiring prolonged follow-ups, as in cancer therapy. The possession of clinical and postmortem records of entire families in one laboratory also fosters the study of human genetics, a subject which should logically be within the province of pathology.

A. F. LIBER, M.D., Amsterdam, N. Y.
Director, Montgomery County Laboratory.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Alleged Failure to Sterilize Instruments Before Removing Pterygium from Eye.—The plaintiff consulted the physician defendant, an eye specialist, with respect to a growth in the corner of his left eye, which the physician diagnosed as a pterygium and advised its removal. Subsequently the physician performed the operation in his office in the presence of the plaintiff's aunt. Both the patient and his aunt testified that the physician "whetted" the instrument with which he operated "on a stone" and then proceeded to operate without either sterilizing the instrument or washing his own hands. This was denied by the physician. Subsequently a "severe infection" developed in the eye, and the patient sustained some loss of vision. Attributing the infection to the alleged failure of the physician to sterilize the instrument or to wash his hands immediately prior to operating, the patient instituted an action for malpractice against the physician. At the trial it was established that the operation performed by the physician was a minor one and when properly performed was ordinarily not followed by the result which here occurred; that for a physician to operate on an eye without washing his hands and sterilizing his instruments would constitute negligence; and that an infection in the part of the body operated on might result from the use of an unsterilized instrument. As stated before, the physician denied whetting the operating instrument on a stone and claimed to have sterilized the instrument and to have washed his hands immediately prior to operating. The physician and the medical witness called on his behalf both testified that instruments such as the defendant

used in the operation in question were not sharpened by the operators but came from the manufacturer already sharpened and in sealed packages. On the other hand, Dr. Kirkpatrick, another eye specialist practicing in the same vicinity, testified that he sharpened his instruments prior to an operation. The evidence adduced was in conflict as to the manner in which the patient's eye might have become infected. The defendant testified that he saw no evidence of infection in the patient's eye when he operated and he believed that after the operation the patient had taken the bandage off, suffered a fall or "gotten a lick" which caused the infection. The patient and other witnesses on his behalf denied that any such incident had occurred. A Dr. Fuller believed that the infection which caused the loss of vision in the patient's eye was probably in existence at the time of the operation. At the close of the evidence the trial court refused to direct a verdict in favor of the physician and after the jury returned a verdict for the patient refused to set that verdict aside. The physician then appealed to the Supreme Court of Arkansas.

In considering the question, said the Supreme Court, of the correctness of the action of the trial court in refusing to direct a verdict in favor of the physician and in refusing to set aside the verdict that was rendered by the jury in favor of the patient, this court must bear in mind these fundamental rules: 1. A court on appeal from a judgment based on a jury's verdict does not pass on the credibility of witnesses. That function is solely to be exercised by the jury, whose decision as to the credence to be given to testimony (except as to testimony contrary to scientific knowledge and mathematical facts) is binding on the appellate court. 2. Where the verdict is supported by any substantial testimony it must, in the absence of prejudicial errors of the trial court, be upheld; and in determining whether there is substantial testimony to support the verdict the evidence must be given the strongest probative force in favor of the party obtaining the verdict that it will reasonably bear. We conclude that, when the testimony in this case is considered in the light of these rules, it must be held that a fact question for the jury was presented by the evidence and that the jury's verdict is supported by substantial testimony.

The physician contended that the evidence was insufficient to justify the verdict, arguing that the charge of negligence against him was not supported by the testimony of any medical expert witnesses. He contended that in a case of this kind negligence cannot be established except by witnesses who are skilled in the practice of medicine. If, answered the court, there could, under the testimony, be any dispute as to the method used in the operation or in the treatment of the patient it would be necessary to establish the correct method by the testimony of medical witnesses but we do not have that situation here. There was no dispute whatever as to what was the proper course to be pursued by the physician in preparing for and performing the operation. It was not denied that it was necessary and proper for the physician to cleanse his hands thoroughly and to sterilize his instruments. The dispute in this case was as to whether or not the physician followed the course which is conceded to be necessary and proper. The physician testified that he did and the patient and his aunt testified that he did not follow this course. No amount of expert testimony could have thrown any light whatever on the real question in this case.

The physician further contended that, even if it be conceded that he failed to sterilize his instruments and to wash his hands, those facts were not sufficient on which to base a finding that such negligence was the proximate cause of the infection. It is not required in a case of this kind, said the court, that the injured party show to a mathematical certainty or to the exclusion of every other hypothesis that his injury occurred as a result of the negligence of which he complains. Herzog, in his "Medical Jurisprudence," discussing the quantum of proof necessary to sustain a recovery for malpractice, lays down this rule:

"It is not necessary to prove beyond a shadow of a doubt that an injury was caused by negligence preceding it, but a showing of strong probability of the causal relation is sufficient. . . . Where negligence and injury are proved, a causal connection between them may be established by circumstantial evidence, by inferences from physical facts" (pp. 161, 162, sec. 186).

In this case it was shown by testimony accepted as true by the jury that the physician failed to wash his hands and to sterilize his instruments before operating on the patient's eye. It was undisputed that a serious and unusual infection followed the operation. Since it appeared that all the causes for this infection, which were suggested by the physician and the medical witnesses called by him, were excluded by testimony which the jury had a right to believe, we conclude that the jury was authorized to find that the infection in the patient's eye was caused by the negligence of the physician.

Accordingly, the judgment in favor of the patient was affirmed.—*Lanier v. Trammell, 180 S. W. (2d) 818 (Ark., 1944).*

Visual Disturbance After Ingestion of Digitalis H M Langdon and R D Mulberger—p 639
Concerning Early Ocular Symptoms of Multiple Sclerosis C A Veasey—p 640
On Biastigmatism T I Pascal—p 644

Diabetic Iridopathy.—According to Clapp diabetic conditions are sometimes associated with changes in the iris Some of these changes are inflammatory, but the majority are not associated with inflammation and should be designated as iridopathy These noninflammatory changes may be confused with malignant melanoma Practically all of the pathologic material available to Clapp showed severe changes in the pigment epithelial layer He presents 2 case histories and reproduces a number of photomicrographs showing changes in the pigmented layer of the iris These changes deserve further study in order to ascertain whether they are limited chiefly to diabetic patients and also their cause

Tobacco-Alcohol Amblyopia.—Carroll reports the case of a woman with tobacco alcohol amblyopia who regained normal vision and normal fields, although she did not decrease her alcoholic intake or improve her diet Vitamin B appeared to be responsible for the satisfactory results When the thiamine was discontinued the amblyopia recurred, and when it was used again essentially normal vision was obtained The author thinks, however, that it is advisable to use a good diet supplemented by the whole vitamin B complex as well as just vitamin B_1 for the best results in the treatment of this condition

Keratoderma Blennorrhagicum Brief Review and Report of Case Treated with Penicillin E M Satulsky—p 361

False Positive Serologic Reactions for Syphilis Due to Smallpox Vaccinations.—Rein and Elsberg investigated the nature and incidence of false positive serologic reactions for syphilis following smallpox vaccinations All soldiers were examined one week after they received smallpox vaccination, and those who developed a vaccinoid or vaccinia reaction were referred for serologic investigation All specimens were subjected to the Kline diagnostic, Kline exclusion, Boerner-Jones-Lukens, Mazzini and Kahn standard flocculation tests and the Kolmer complement fixation test One hundred and twenty nine soldiers developed a vaccinoid or vaccinia reaction following the smallpox vaccination, of whom 58 (44.9 per cent) showed doubtful or positive tests with one or more of the serodiagnostic procedures employed The authors stress that since biologic false positive reactions occur with some frequency following smallpox vaccinations, it is important to rule out that possibility before antisyphilitic treatment is instituted Irreparable physical and psychologic damage has been produced by an ill considered or hasty diagnosis If treatment is started prematurely, the evidence which could have finally led to an accurate diagnosis is often obscured Serologic tests may become negative with a small amount of treatment, and one is at a loss to know whether the seronegativity represents a response to therapy or merely reflects the fact that the patient has never had syphilis Much time can be saved by thoroughly studying the soldier with an unexplainable positive serologic reaction before the diagnosis of syphilis is established and treatment is instituted

Penicillin Therapy of Sulfonamide Resistant Gonococcic Infections.—Cohn and Kornblith employed penicillin in the treatment of 113 men with sulfonamide resistant gonococcic infections Two schedules of penicillin therapy were tested In both schedules a total dosage of 100 000 Oxford units of penicillin, administered intramuscularly, was found both necessary and sufficient for bacteriologic cure In the first schedule treatment was divided over a period of six hours, an initial injection of 50,000 Oxford units of penicillin was followed by two intramuscular injections of 25,000 Oxford units each at three hour intervals Eleven patients who received this schedule of therapy became bacteriologically negative within four hours, and in the second schedule of treatment 102 patients received the total amount of 100,000 Oxford units of penicillin within a period of four hours A total of 100 cases in this group responded promptly to one course of therapy Eight of these patients were reinfected, and 5 of them again responded to a second course of penicillin therapy Of the 113 cases studied, 94 (83 per cent) presented complications There were 8 cases of epididymitis and 86 cases of prostatitis The acute symptoms of epididymitis, such as pain fever and malaise subsided within three days among 7 of the 8 cases observed Swelling and induration of the epididymis and inflammatory hydrocele persisted for variable periods of one to four weeks Acute symptoms and signs of prostatic involvement subsided promptly after penicillin therapy The more chronic infiltrations improved moderately during five weeks of observation There was no consistent correlation between the clinical findings in the prostate and the corresponding microscopic findings of wet smears from prostatic secretions Reactions to penicillin therapy were of a mild and transitory character The authors conclude that the therapy of complications of gonococcic infections does not necessarily end with the administration of the penicillin alone

Tuberculin Testing of Medical Students Reaction to Tuberculin of Second Year Medical Students at College of Physicians and Surgeons Columbia University M M Steinbach and C J Duca—p 478

Minimal Tuberculous Lesions of Lung.—Reisner and Downes studied the behavior of the minimal lesion of tuberculosis during a period of about five years, which was the length of time for which about 50 per cent of the patients were followed up, the others being observed for longer or shorter periods The material was collected from the ambulatory chest

clinics of the New York City Department of Health and consists of 469 persons, of whom 200 were male and 269 female. Since analysis by sex showed no indication that females were more liable to progressive disease than males, the data for the two sexes have been combined. None of the patients were less than 10 years of age, 24 per cent were between 10 and 25, 58 per cent were in the age group between 25 and 44 and 18 per cent were 45 years or older. The majority of patients showing involvement of minimal extent are asymptomatic and aside from roentgenologic findings present few objective criteria for evaluation of their clinical significance. An appraisal of the clinical importance and presumable prognosis of the minimal tuberculous lesion requires a qualitative differentiation of the type of lesion. Lesions of the exudative or exudative-productive type are characterized by an unstable behavior and a tendency to progression. Progression was observed in about one half of the white patients and in 61 per cent of the nonwhite patients. Lesions of productive-fibrotic or fibrocalcific character have shown a stationary behavior in the majority of instances, progression or instability having occurred in only 5 per cent of the white and 14 per cent of the nonwhite patients. Lesions of the fibrocalcific type showed the highest rate of stability, progression being an exceptional occurrence. If the character of the lesion is considered, age per se is not important as far as the risk of developing progressive disease is concerned. The age factor merits consideration from the point of view of prognosis to the extent that lesions of exudative character, representing a presumably early and potentially progressive type of involvement, are more apt to be found in the young age groups. Supervision of patients with minimal tuberculosis should be on a selective basis and should take into account the risk of progressive disease as related to the character of the lesion.

Diasone Therapy of Pulmonary Tuberculosis.—Benson and Goodman administered diasone for from 120 to 160 days to 22 patients with pulmonary tuberculosis. Only 4 patients may possibly have benefited from the drug. Two patients in the series died while on the diasone therapy. Another patient developed an exfoliative dermatitis necessitating withdrawal of the drug. A variety of toxic and untoward responses to diasone were observed, including cyanosis, anemia, dermatitis, fever, jaundice, tremors, diplopia and enlargement of the thyroid. Diasone is an experimental drug which is currently being investigated. It should be employed only under the most rigid clinical and laboratory control.

Anoxemia and Hemopoietic Activity.—Hurtado and his associates describe investigations of the influence of temporary, intermittent and chronic anoxic anoxia (anoxemia) on the morphologic and other characteristics of the circulating blood of several series of healthy and diseased male subjects at sea level and various altitudes. They found that exposure to a low pressure environment causes a polycythemic response. In general the level of polycythemia is directly proportional to the degree, duration and continuity of the anoxic stimulus. There seems to be a limit for the hematologic response to the anoxic stimulus. When this is extremely severe a decrease rather than a further increase is observed in polycythemia. The level of hemoglobin in the circulating blood may be one of the many factors which tend to preserve the internal stability against the disturbing influence of a constant lowering of the oxygen tension in the inspired air. The polycythemia associated with the anoxemia of high altitudes is absolute in type. The elevation in the total blood volume, which at times reaches high values, is due to an increased red cell volume. The polycythemia observed on arrival at high altitudes seems to be due to release of stored blood and hemoconcentration; that corresponding to a repeated or constant exposure to a low pressure environment is related to an erythropoietic hyperactivity. The polycythemia associated with a constant or intermittent anoxemia tends to show a proportional elevation in the circulating reticulocytes and in the serum bilirubin. The latter characteristic suggests that an increased rate of cellular destruction parallels the increased formation, but other factors, such as insufficiency of the liver in excretion of pigment, due to the anoxic condition, may also be a factor in the hyperbilirubinemia. The stimulating influence of anoxemia on the hemopoietic system is restricted to the formation of red blood cells and hemoglobin. Leukopoietic activity is not affected. Chronic anoxemia does not modify the erythropoietic activity permanently. When a person who has lived since birth at high altitudes is brought down to sea level he shows after some time blood characteristics similar to those found in persons who have always lived under the latter environmental conditions. Comparative study of the polycythemia of high altitudes and the polycythemic processes observed at sea level indicates that (*a*) in cases of anoxemia at sea level due to pulmonary changes the polycythemic response tends to be less than with corresponding degrees of arterial oxygen unsaturation at high altitudes, except in cases of Ayerza's disease; (*b*) it is not likely that the causative mechanism of polycythemia vera is related to the existence of an anoxic stimulus.

Ocular Sequelae of General Anesthesia.—Berens and Fonda report the case of a man aged 26 who was operated on for pilonidal cyst under ethylene-ether anesthesia. Prior to this operation the patient's eyes revealed no abnormality. Within twenty-four hours after the operation the patient experienced diplopia when looking upward. On the following day the diplopia was present while he was reading. Onset of ptosis was coincidental with the diplopia. Later examinations revealed paralysis of the superior rectus muscle, exophthalmos, pseudoptosis and fibrosis of the inferior rectus muscle. The most probable explanation of the ocular symptoms was that an embolism of the artery supplying the superior rectus muscle occurred. Fibrosis of the inferior rectus muscle may have been caused by the secondary contracture associated with embolic myositis. There may be no proved causal relationship between the ethylene-ether anesthesia and the sudden onset of diplopia and the proptosis, but the short interval of less than twenty-four hours between the occurrence of the ocular symptoms and the operation is highly suggestive of a close relationship.

Cancer of Larynx.—Cancer of the larynx is 100 per cent fatal without treatment, but according to Jackson and Norris the prognosis of treated cases is better than in cancer of most other parts of the body. The cases treated surgically should be divided into those treated by laryngofissure (or partial laryngectomy) and those treated by total laryngectomy. The mortality of the form of laryngofissure used by the authors should be practically zero. In their clinic not a single patient has died of this operation for fourteen years; and during this time 148 laryngofissures have been done. According to the literature, the mortality of total laryngectomy is certainly much higher than that of laryngofissure, but in the last 70 laryngectomies performed by the authors there has not been a single operative fatality. A recent analysis of the end results in a series of 150 patients with cancer of the larynx treated at the Temple University Hospital by surgery and irradiation during the period 1930 to 1937 inclusive showed a combined five year cure rate of 64 per cent. Of the 101 patients with intrinsic lesions who underwent either laryngofissure or laryngectomy, 80 patients obtained at least a five year cure. Nine patients with extrinsic lesions in whom laryngectomy was done died. During the same period 34 patients were treated by irradiation (protracted fractional technic), 22 of them intrinsic and 12 extrinsic. In the intrinsic group a 59 per cent five year cure rate was obtained, in the extrinsic group a 25 per cent five year cure rate.

Ligation of Inferior Vena Cava in Pulmonary Embolism.—*O'Neil* suggests that when concurrent phlebothrombosis exists in both lower extremities and has extended to or above the inguinal ligament and when pulmonary embolism has occurred and its course is not evident, interruption of the inferior vena cava is indicated. The fact that aseptic thrombosis may exist in the large pelvic vessels and initiate a serious embolism should not be overlooked. If an operation is to be performed only on suspicion of deep venous thrombosis, the best assurance that can be given for the patient's safety is the highest possible ligation compatible with adequate venous return.

Primary Tumors of Liver. W. N. Warvi.—p. 643.

Mechanism of Shock.—*Fox and Keston* used radioactive sodium to explore whatever changes might occur after shock from burns or trauma. Two types of experiments were conducted. In one type animals were prepared with radiosodium given in isotonic solution of sodium chloride so that the body sodium was in equilibrium and tagged with the isotope. Shock was produced twenty hours later, and the concentration of radiosodium in the tissues and organs was determined in the animals during shock but not when moribund. In a second type of experiment shock was produced first and the animals were then treated with isotonic saline solution containing some radiosodium. About twenty hours later, on recovery from potentially fatal shock (as judged by death of untreated controls), the concentration of radiosodium was determined in tissues and organs. The water content of all tissues sampled was also measured by drying the tissues at 110 C. for eighteen to twenty-four hours. Similar analyses were performed in parallel control animals which had not been injured but which had received equal doses

of radioactive sodium. The experiments were made on mice. They demonstrated the great accumulation and side tracking of sodium in injured tissues with subsequent reduction in plasma volume characteristic of traumatic shock. Conversely, treatment with an amount of isotonic sodium solution approximating one-half the extracellular volume restored this volume. This explains the successful treatment of shock in animals and in man with large volumes of isotonic solutions of sodium salts.

Testosterone Propionate in Mammary Cancer.—Prudente used testosterone as a postoperative measure in treating 63 patients with mammary cancer who had previously been operated on. As controls, 64 cases are reported in which the breast had been removed by the same technic of radical surgery and in which testosterone propionate was not used. All 127 cases were operable. The results obtained, as gaged by the survivals of three, four and five years, are about 100 per cent better than those observed after operation only. This fact indicates that testosterone propionate exercises a protective or prophylactic action against recurrences of surgically treated mammary cancer. Very high doses of testosterone propionate, up to 175 mg. a week, may and should be used after operations for mammary cancer, and this treatment should be continued through many years. The principal criterion for the selection of the dosage is the grade of histologic malignancy of the tumor. The side effects following this therapy are of secondary importance. They consist of virilization and of disturbances of menstruation. In patients between 40 and 50 years of age who are still menstruating, early cessation of menstruation is often observed.

Causalgia.—Mayfield and Devine report 15 cases of causalgia found among a group of 737 peripheral nerve injuries. The nerve lesion was incomplete in each case of causalgia. This syndrome has not been seen in any individual in whom the nerve was completely divided. Burning pain was a constant complaint and was usually immediate in onset. The median or sciatic nerve was involved in each instance. Certain patients showed vasoconstriction in the causalgic limb; others showed vasodilatation. The trophic changes and response to warm or cold moisture and to hyperthermia varied, depending on the blood flow. Twelve patients were relieved by sympathectomy of the involved limb; 1 was cured by artificial fever therapy and 2 recovered spontaneously. Direct surgical attack (neurolysis) on the injured nerve, which was performed in 5 cases, and periarterial sympathectomy at the level of the injury, performed in 3, have not been of benefit. Procaine block of the sympathetic chain affords complete relief temporarily and should be repeated two to three times, although no case in this series has shown any lasting benefit from this procedure. Sympathectomy (preganglionic) gave immediate and lasting relief to 12 patients. Sympathectomy should be done early to prevent stiffness of joints due to disuse. The personality changes present during the painful stages are secondary to the pain. There is no evidence in these cases that there is a predisposing constitutional psychic factor in causalgia.

Transmesenteric Strangulated Hernia.—Desjardins presents the case of a man aged 47 who had always been in good health but who suddenly during the night had a violent attack of abdominal pain with vomiting. Examination revealed a severe state of shock, hypothermia, rapid pulse, muscular rigidity over the whole abdomen and the presence of a mass in the hypogastric region and the iliac fossae. On operation a strangulated transmesenteric hernia was found, 60 inches of the small intestine was resected and an ileocecal anastomosis was made. The postoperative course was stormy; there was a localized peritonitis, a pulmonary abscess and purulent pleurisy. A drainage pleurotomy was done, but the patient died thirty-nine hours after the onset of the disease. These hernias are not frequent, Hausmann and Morton having found only 52 cases among 467 cases of internal hernias. Diaphragmatic hernias are the most frequent among the internal types of hernia. The transmesenteric hernias may supervene at any age and in both sexes. They do not have a sac and consist only of the passage of a loop of intestine through a gap in the mesentery.

Reaction of Degeneration in Peripheral Nerve Lesions.—Pollock and his associates describe the data obtained from the examination of denervated and recovering muscles in cats as related to the characteristics of the reaction of degeneration; they compare such data with some obtained in human subjects and discuss the usefulness of the reaction of degeneration as a diagnostic and prognostic sign. For the most part Erb's description of the characteristics of complete reaction of degeneration have been confirmed by their studies. They emphasize that faradic stimulation is effective throughout degeneration, denervation and regeneration, provided sufficient amperage is employed. The changes of response to galvanic stimulation of "infinite time" which characterize complete reaction of degeneration are (1) hyperirritability of muscle to galvanic stimuli, (2) sluggishness of relaxation of the contraction wave, (3) lessening of the ratio between amperage necessary to produce tetanus and rheobase to almost unity and (4) increase of efficacy of the anodal closing stimulus to equality with the cathodal closing stimulus. Unequivocal signs of recovery are (1) a sudden increase in rheobase, (2) an increase of ratio between the amperage necessary to produce tetanus and rheobase and (3) an increase in efficacy of the cathodal closing stimulus as compared with the anodal closing stimulus. The electrical sign of recovery characterized by the sudden increase of rheobase antedates the recovery of motion and sensation for long periods, in man by many weeks. The other signs likewise antedate other clinical signs of recovery. Electrotherapy has no effect on the response of muscles to electrical stimuli.

Functional Enuresis in the Army.—Shlionsky and his co-workers report observations on 100 men with functional nocturnal enuresis whom they studied in an army training camp in the United States. They found that the educational and occupational background of these men was in general below average. Most of the men had lived in rural communities and had used outdoor toilets in childhood. There was a high incidence of enuresis in the immediate families of these soldiers. A considerable number gave a history of disruption of the home or of exposure to various other unfavorable types of environment in childhood. A relatively high percentage of the men were below average intelligence. The majority manifested in addition to the enuresis various neurotic tendencies and personality disorders. Most of the men showed evidence of emotional immaturity. Not infrequently there was persistence or recurrence of some of the various neurotic traits of childhood, such as nightmares, nail biting, stuttering, fear of the dark, sleepwalking and talking in the sleep. Functional backache was a common symptom. Virtually none of the patients had ever received adequate medical attention for the enuresis prior to army service. Functional enuresis is generally but one manifestation of a lifelong pattern of neurotic behavior or personality maladjustment and is not infrequently associated with adequate intelligence. Apart from the consideration that the symptom of enuresis itself creates a difficult situation in the service, it is apparent that the majority of enuretic adults do not possess the qualifications necessary for the successful performance of duty in the armed forces.

*Massive Dose Tryparsamide by Intravenous Drip Method in Treatment of Trypanosomiasis. A. F. Fowler.—p. 297.

Treatment of Amebiasis.—According to Adams, large numbers of men overseas are being exposed to infection with Endameba histolytica. Some suffer from gross clinical attacks of amebic dysentery, others give no such history but are found to be infected on routine examination of the stools. The author thinks that it is improper to neglect a detected infection with E. histolytica until clinical manifestations make their appearance. To do so is to condemn many patients to subsequent unnecessary ill health with the possible development of a major disaster such as an amebic liver abscess. Furthermore, such patients are liable to disseminate the infections to others. They should be regarded as latent cases requiring early treatment. To discover these infections necessitates routine repeated stool examination. Emetine has a more specific action on this infection than any other drug. Emetine alone by injection will not sterilize an infection in more than a minority of cases; if it is given unwisely the infection becomes resistant to the drug in all forms and less amenable to treatment. Therefore the use of emetine by injection should be restricted to the control of clinically acute manifestations, and the minimum amount necessary to achieve this end should be given. The eradication of an intestinal infection must be attempted by the use of a variety of drugs, including emetine preparations, all of which have some action on the infection. These drugs should be given together because their combined effect is greater than that of any single drug alone, and they must be given as early as possible over an adequate period. Three weeks of such treatment ensures a high proportion of cures in cases not previously repeatedly treated subcuratively.

Survival of Transfused Red Cells in Blackwater Fever.—Foy and his associates found that red cells transfused from compatible group O donors into hemolyzing cases of blackwater fever were destroyed in the blackwater fever circulation just as were the patient's own cells. Red cells taken from a hemolyzing group O case of blackwater fever and transfused into a normal group A person had a survival time of only six days, indicating that there is some defect in the blackwater fever red cells that renders them more susceptible to destruction even in normal circulations. Plasma taken from a hemolyzing case of blackwater fever and transfused into a patient with an acute attack of malaria failed to produce signs of hemolysis. Normal red cells transfused into patients with hemolytic jaundice have a normal survival time but hemolytic jaundice cells transfused into normal circulations have a shortened survival time, indicating that in this disease the primary defect is in the red cells. The hemolytic processes in blackwater fever and hemolytic jaundice may be of a fundamentally different nature. Lysolecithin fragility is increased in both blackwater fever and hemolytic jaundice, making it appear that this may be a better guide to hemolytic tendencies than is saline fragility or spherocytosis.

Tryparsamide by Intravenous Drip.—The results obtained in the treatment of early syphilis by massive dose intravenous drip arsenotherapy prompted Fowler to treat cases of trypanosomiasis similarly, using the pentavalent arsenical tryparsamide. He employed the intravenous drip method in 42 consecutive cases of trypanosomiasis. This method requires hospitalization but reduces the time of treatment from twelve weeks or more to about twelve days or less. The method produces rapid sterilization of the blood and lymph nodes and it is unlikely that treated cases will become arsenic resistant. Children and young adults tolerate the treatment well. The aged are unsuitable for such treatment. Brief case histories are given of 24 patients who were examined from four to seven months after treatment. Although it is impossible to estimate the curative effect of the treatment without further examination of the cases over a period of eighteen months, the results in the 24 cases appear to be encouraging.

Acta Radiologica Stockholm

25:251-378 (Sept. 20) 1944. Partial Index

Radiologic Study of Cecocolic Invagination of Adult. R. J. Gilbert and J. Garcia-Caldéron.—p. 251.
*Osteochondritis Dissecans of Head of Femur. I. Hermodsson.—p. 269.
*Treatment of Leukemia with Artificial Radioactive Sodium. J. E. Thygesen, A. Videbaek and I. Villaume.—p. 305.
Cystic Form of Cancerous Metastases of Bone. B. Engfeldt.—p. 317.
Internal Biliary Fistulas: 2 Cases. E. Brandel.—p. 333.

Osteochondritis Dissecans of Head of Femur.—Hermodsson presents histories of 5 cases in which he made careful x-ray studies and reviews cases from the literature. He differentiates between primary and secondary cases of osteochondritis dissecans of the head of the femur. To the latter he assigns cases caused by disorders such as cretinism and fracture of the neck of the femur. He stresses that in all cases of primary osteochondritis dissecans there exist x-ray signs indicating that a more or less extended osseous aseptic necrosis was present in the head of the femur. He offers the following explanation of the pathogenesis: There exists an aseptic necrosis. This is not completely reorganized and a reduced resistance remains. Under the influence of strain or trauma a pathologic fracture results at the most exposed site of the femoral head, the upper pole. This engenders a limited aseptic necrosis and this in turn results in osteochondritis dissecans, as was shown by Axhausen. This theory of pathogenesis explains the fact that most of the patients are laborers. The author describes some cases which represent an intermediate form between Perthes' disease and osteochondritis dissecans and suggests that if Perthes' disease is designated as osteochondritis deformans or osteochondrosis deformans these intermediate forms should be designated as osteochondritis deformans dissecans or osteochondrosis deformans dissecans.

Treatment of Leukemia with Artificial Radioactive Sodium.—Thygesen and his associates gave intravenous injections of a solution of radio sodium, Na^{24}, to 7 patients with chronic lymphatic leukemia. Except in 1 of the cases, which later proved refractory also to roentgen treatment, the fall in the white cell counts and the remissions obtained were similar to those after exposure to roentgen rays. The patients showed subjective as well as objective improvement. In 2 of the patients the improvement has been manifest for several months, but otherwise the time is too short to be able to judge the duration of the effect. In addition to the 7 cases of leukemia, 1 case of polycythemia vera was treated with radio sodium; here the effect was slight and only temporary.

Book Notices

Clinical Cystoscopy: A Treatise on Cystoscopic Technic, Diagnosis, Procedures, and Treatment. By Lowrain E. McCrea, M.D., F.A.C.S., Associate Professor of Urology, Temple University Medical School, Philadelphia. In two volumes. Drawings by B. Engle Shaffer. Cloth. Price, $25, per set. Pp. 534; 535-1056, with 667 illustrations. Philadelphia: F. A. Davis Company, 1945.

This treatise on clinical cystoscopy is a thorough presentation on the subject in two beautifully printed volumes. The classification of the text is good. The chapters are well arranged, carefully balanced and properly organized. The volumes read easily and are profusely illustrated. The drawings, paintings and photography, especially the colored photography of the cystoscopic appearance of the bladder diseases, are superb.

In the first volume are seventeen chapters, the first four of which take up the history of the cystoscope, the various types of cystoscopic instruments, indication and contraindication for cystoscopy, preparation of the patient for cystoscopy and the method of performing a cystoscopy. In chapter five the cystoscopic picture of the normal bladder is discussed. In the next seven chapters all the known diseases of the bladder are considered and these are discussed in a thorough, concise manner. Beautiful paintings or colored photographs illustrate the cystoscopic pictures of the disease. A chapter on the neurogenic bladder follows with a good classification of these disturbances, supplemented by various forms of treatment. In the chapter on prostatic hypertrophy the author's opinions concerning the indications and contraindications for transurethral resections may not be acceptable for many other urologists. The last three chapters discuss the ureter: its anomalies and diseases.

In the second volume are fourteen chapters in which surgical and medical diseases of the kidneys are discussed. One entire chapter is devoted to the subject of kidney function tests. Urology in children and the female requires two chapters for its comprehensive presentation. The last chapter concerns roentgenography in urology. More consideration might have been given to excretory urography. For instance, little effort has been made to discuss the physiologic principles of this diagnostic procedure. There are those who are not in complete agreement with the author in his discussion of the comparative value of retrograde and excretory pyelograms. At the end of each volume is an extensive and authentic bibliography arranged to coincide with the chapters.

These two volumes give the best presentation on clinical cystoscopy that the reviewer has seen and can be highly recommended to those interested in or desiring to learn more about cystoscopy. Even the trained cystoscopist can find much of value in them.

Penicillin hakkında in vitşo arastirmalar I-III (Almanca bölüm). Penicillin-Studien in Vitro I-III. Von Julius Hirsch, Hygiene-Institut der Universität Istanbul. Compte rendu annuel et archives de la Société turque des sciences physiques et naturelles, Fasc. 12 (Separatum). Paper. Pp. 88, with illustrations. Istanbul, 1945.

The monograph by Professor Hirsch deals with the author's theory of the mode of action of penicillin, the manometric test of penicillin activity developed by him and with a method of growing crude penicillin. Hirsch demonstrated in his experiments in vitro that penicillin has neither bactericidal nor bacteriostatic effect. Penicillin was shown to exert an effect only in bacterial cultures capable of multiplying. This effect becomes evident after multiplication of the bacteria has progressed for some time. In proportion to the added concentration of penicillin, the multiplication sooner or later suddenly changes into a logarithmically progressing process of destruction which may lead to lysis of the staphylococci. Generation of cells which develops in the presence of penicillin is incapable of further multiplication and their individual life span is abnormally short. These staphylococci show the morphologic changes described by Gardner. This effect of penicillin on the staphylococcus culture is a qualitative rather than a quantitative effect; it results in a generation of abnormal, sterile cells which rapidly die. The author considers this a specific action of penicillin and designates it as the "degenerative effect." This degenerative effect is characterized by a respiratory curve which, following the addition of penicillin, continues to increase for a while in normal logarithmic progression. The degenerative effect is the only effect of penicillin: a carefully purified barium salt produces exclusively this specific degenerative effect over a wide range of concentration (from 0.08 to 50.0 units per cubic centimeter). Hirsch also showed that in unpurified penicillin-barium salt a second antibiotic factor exists. This factor has a typical bacteriostatic action. It accompanies penicillin in the culture filtrates of penicillium notatum Fleming. The interference by this factor with the specific effect of penicillin is quite evident even in diluted crude penicillin.

The manometric penicillin test developed by the author depends on the respiration rate (oxygen consumption—by time unit) of staphylococcus cultures in the presence of penicillin. The addition of penicillin to staphylococcus cultures results in an increase which is limited in time and is followed by logarithmic decrease. The oxygen deficit can be utilized for the determination of the activity of crude penicillin and of penicillin preparations.

Hirsch found that the addition of concentrated watery extracts of wheat bran to the Czapek-Dox medium (5 to 7.5 per cent of wheat bran or BK dry substance in the culture medium) produces in from eleven to twelve days a crude penicillin with from 50 to 60 units per cubic centimeter. A good penicillin crop can be obtained only in small cultures with limited surface. He was able to overcome the inhibition of the surface growth of the fungus by the method of a closed screen of floating glass bulb rods. By this method it is possible to produce mass cultures of the Fleming strain on culture mediums that contain wheat bran extract and that are of any desired surface. They produce, after eight days, a crude penicillin of at least 50 to 60 units per cubic centimeter.

This monograph is an important contribution to the new science of antibiotics. Although published in Turkey, it is written in German and should therefore be accessible to workers in this field.

Anatomy and Physiology for Students of Physiotherapy, Occupational Therapy and Gymnastics. By C. F. V. Smout, M.D., M.R.C.S., L.R.C.P., Senior Lecturer and Acting Professor, Department of Anatomy, University of Birmingham, and R. J. S. McDowall, M.D., D.Sc., Professor of Physiology, University of London, King's College. Cloth. Price, $8. Pp. 418, with 288 illustrations. Baltimore: William Wood & Company, 1944.

The authors state that this book is not intended to be used as a substitute for the standard anatomy and physiology textbooks. The amount of significant information presented in the volume, however, would hardly warrant its general use as a supplementary textbook. The cost of the book may be prohibitive for students. The most instructive chapters are those entitled Living Anatomy and Muscles in Action. The physical therapist, occupational therapist and teacher of physical education need a concentrated and sufficiently detailed diagrammatic and photographic presentation of surface anatomy as it applies to these fields. This section is well done but not complete. The chapter Muscles in Action is interesting for the diagrammatic and outline presentation of muscle function in common activities. The book would be more valuable if this section had been considerably enlarged. The section on physiology is not sufficiently related to the three fields under consideration to be of value as supplementary material, nor does it cover the subject thoroughly enough for a basic textbook.

Health Research in Industry. (Proceedings of a Conference on Industrial Health Research held at the London School of Hygiene and Tropical Medicine, 28th September, 1944.) Medical Research Council, Industrial Health Research Board. Paper. Price, 6d. Pp. 27. London: His Majesty's Stationery Office, 1945.

This bulletin contains a series of papers presenting the views of the Medical Research Council and of management, medicine and trade unions on the present state of organization and desirable evolution of industrial health services. The opinions expressed indicate that at least in respect to health matters not much controversy remains. Neglect of manpower is poor business—and there no longer is room in competitive industry for the bad manager. Labor asks for liberalization of occupational disease benefits, better working environment and intensified research. The organization and early experiences of the Department of Research on Industrial Medicine of London Hospital are described, as is also the work of the applied psychology unit of Cambridge University.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DIAGNOSIS OF THYROTOXICOSIS

To the Editor:—I should appreciate comment on the following statement, the origin of which I cannot find but the value of which I believe to be significant: "Any patient with hyperthyroidism has a tachycardia while sleeping and has a widened pulse pressure. If the pulse at rest is normal and/or if the blood pressure is normal, the diagnosis of thyrotoxicosis is excluded." MC, U.S.N.

ANSWER.—The statement that a normal pulse rate and a normal blood pressure at rest exclude the diagnosis of thyrotoxicosis is true in most instances but not in all. In making the diagnosis of toxic goiter it is not sufficient to rely on the pulse rate and blood pressure, and there is too much tendency at the present time to do so; for example, one pharmaceutical house recently considered the desirability of distributing among physicians a chart for determining the basal metabolic rate from the product of the pulse pressure and the pulse rate. The diagnosis of thyrotoxicosis is usually not difficult, but in doubtful cases attention must be paid to many factors and it is sometimes necessary to observe the response of the basal metabolism to iodine or thiouracil before arriving at a definite conclusion.

SMOKING IN PULMONARY TUBERCULOSIS

To the Editor:—In the book of instructions to patients at a tuberculosis institution it is stated that tobacco is injurious to patients with tuberculosis of the lungs. Many practicing physicans apparently disagree with this opinion. Is there any authentic work on this subject? M.D., Virginia.

ANSWER.—Statistical studies have not shown tuberculous infection or disease to be more frequent in users of tobacco than in those who abstain. Well controlled quantitative studies of the effect of tobacco on the course of pulmonary tuberculosis are lacking. Among tuberculous patients it has been found that those who smoke are apt to have a higher incidence of laryngeal involvement and that such complications appear to be adversely affected by persistence in smoking. Acceleration of the pulse rate, frequent extrasystoles and accentuated sinus arrhythmia, hacking cough, hoarseness and diminished appetite, which so often result from tobacco smoking, may simulate or even accentuate the symptoms of tuberculosis, whether or not they exert much influence on the actual course of the disease in the average patient. The course of pulmonary tuberculosis is so variable and is influenced by so many factors that it is not easy to demonstrate an important or clearcut effect from any one item or detail in the regimen of treatment. Most phthisiologists, however, are convinced that smoking can do no good and may do harm sufficiently often to advise against it.

EXSTROPHY OF BLADDER

To the Editor.—How early in life may a child be operated on safely for exstrophy of the bladder? L. Edward Giovine, M.D., Woodside, N. Y.

ANSWER.—The operation for exstrophy of the bladder which is generally accepted consists in reimplantation of the ureters into the sigmoid, with excision of the vesical tissue. There is some difference of opinion as to the most favorable age at which a child should be operated on. Many surgeons have waited until the child is 3 or 4 years of age before advising operation. Recently operation has been advised for infants less than 1 year of age; in fact, preferably under 6 months. The reasons given are (1) to avoid the possibility of ascending infection, (2) tolerance to operation by the infant and (3) to obviate the psychologic impression of physical defect on the older child. Some surgeons however believe that, because of diminutive size of the ureteral and other tissues, the technical difficulties are greatly increased in infancy. It is open to question whether serious pathologic complications in the urinary tract develop often prior to 3 years of age.

HOMOSEXUALITY

To the Editor:—Is homosexuality thought to be a congenital or an acquired condition? Paul Sizemore, M.D., Durant, Okla.

ANSWER.—Despite the fact that some homosexuals have rather obvious characteristics of the opposite sex both in physical appearance and in character traits, the majority of psychiatrists and sexologists believe that homosexuality is an acquired condition and that the main etiologic factors are psychogenic rather than genetic.

All human beings are to varying degrees bisexual, and under certain environmental circumstances homosexual behavior may break out in persons whose previous behavior has been consistently heterosexual. This phenomenon is not uncommon in men confined to a completely homosexual environment as, for example, a prison, or among adolescents living in institutions limited to one sex.

Many homosexuals have had or are capable of having heterosexual experiences. During psychiatric treatment it is learned that the homosexual has the usual heterosexual wishes and longings but these are repressed because of deep seated fears of heterosexuality. Childhood sexual experiences of a fearful nature, especially parental attitudes which are prohibitive, threatening and punitive toward the normally developing sexuality (the expression of sexual curiosity and sexual play such as masturbation) may in the child shift the scale toward homosexuality. As such a child grows up he retreats from heterosexuality to homosexuality because of previous fearful associations with heterosexuality.

A recent study of hermaphrodites by Ellis (The Sexual Psychology of Human Hermaphrodites, *Psychosomatic Med.* **7**:108 [March] 1943) has thrown more light on the importance of psychogenic and environmental factors in homosexuality. He found that the hermaphrodite assumes the sexual role that accords primarily not with his or her internal or external somatic characteristics but rather with his or her masculine or feminine upbringing. Therefore heterosexuality and homosexuality in hermaphrodites as in the nonhermaphrodite are primarily caused by environmental and not by endocrine or other physiologic factors.

Although the treatment of homosexuality is a difficult task, thoroughgoing psychiatric treatment which aims at uncovering and correcting psychogenic factors offers a much better hope for cure than treatment with injections of endocrine preparations.

TOXICITY OF CHLORINATED NITRILS

To the Editor:—Could you give me any information regarding the toxicity of chlorinated nitrils? F. F. Boys, M.D., East Chicago, Ind.

ANSWER.—It was shown by Liese (*Ztschr. f. hyg. Zool. Schädlingsbek.* **33**:1, 1941; *Chem. Zentralbl.* **1**:2713, 1941) that trichloracetonitrile (CCl_3CN) is somewhat less toxic than sulfur dioxide in that a concentration of 2.9 Gm. per cubic meter (490 parts per million) was comparatively well tolerated by mice, whereas sulfur dioxide in concentrations of 2.76 Gm. per cubic meter (1,031 parts per million) was absolutely fatal.

According to Meurice (*Arch. internat. pharmacod.* **7**:11, 1900) the fatal dose of chloral nitrile ($CCl_3CH(OH)CN$) with subcutaneous injection for pigeons is 0.012 mg. per gram of body weight and that of the corresponding nonhalogenated nitrile (lactonitrile, $CH_3CH(OH)CN$) is 0.010 mg. per gram of body weight, whereas that of potassium cyanide is 0.0015 mg. per gram of body weight. Hunt (*Arch. internat. pharmacod.* **12**:497, 1904) determined the fatal dose of chloral nitrile with subcutaneous injection for mice as 0.023 mg. per gram of body weight, whereas the fatal dose of hydrocyanic acid was 0.005 mg. per gram of body weight. It appears, therefore, that the chlorinated nitrile is of the same order of toxicity as the unsubstituted nitrile and that both are about five times less toxic than hydrocyanic acid, causing the same or at least a similar toxicologic picture.

CONVULSIONS IN CHILDREN

To the Editor:—Do children with chorea ever have convulsions? Are there any other conditions that are accompanied by the emotional and physical disturbances associated with chorea? M.D., Ohio.

ANSWER.—Convulsions are not usually a symptom or a part of chorea in children. Although a convulsive seizure may usher in the onset of an acute chorea, it is hardly ever seen as a part of it. There are other conditions that may have convulsive seizures in association with choreiform movements. These are encephalitis, meningoencephalitis, lesions of the corpus luysi (hemiballisms) and various degenerative diseases of the basal ganglions.

HUMAN ENCEPHALITIS IN THE YAKIMA VALLEY, WASHINGTON, 1942

WITH FORTY-NINE VIRUS ISOLATIONS (WESTERN EQUINE AND ST. LOUIS TYPES) FROM MOSQUITOES

W. McD. HAMMON, M.D., DR. P.H.

AND

BERNARD BROOKMAN, A.B.
SAN FRANCISCO

In the Yakima Valley, Washington, a series of four annual epidemics of encephalitis have occurred. The present report is concerned with the last of these outbreaks (1942), which is the third studied and reported. The findings of this investigation warrant reporting, particularly since the cases were followed more carefully clinically, since a higher proportion of both early and late phase serums were obtained for neutralization tests, and especially since 49 virus isolations were made from mosquitoes caught in the epidemic area. Identification of these viruses and repeated titrations of antibody in the patients' serums have greatly delayed this report, but during the interval certain other significant data have been collected and experiments performed which contribute greatly to the analysis of the problem. Furthermore, it may now be recorded that two succeeding summers (1943-1944) have passed during which there has been no encephalitis epidemic in the valley. Only 1 human case was recognized in 1943. This terminated fatally and we succeeded in obtaining from the brain the first strain of western equine virus to be isolated directly from man from this area. Studies are in progress to attempt to discover what may have brought about this break in the series of epidemics.

During the late summer of 1942, 28 cases of encephalitis were sufficiently well diagnosed to be included in this series. These include cases of the western equine and St. Louis types and probably at least one other whose etiologic agent has not been identified. We [1] reported 31 cases in 1939, 58 in 1940 and 26 in 1941. Chart 1 shows the seasonal distribution of cases for the four years. From the standpoint of temperature, humidity and mosquito prevalence the summer of 1942 did not vary significantly from the two previous years; the temperature rose to 90 F. or above almost every day, there was no measurable precipitation, and mosquitoes bred abundantly in many places, principally as a result of careless irrigation practices.

CLINICAL OBSERVATIONS

Diagnosis in all but 1 case was confirmed by some laboratory procedure. In most instances the spinal fluid was examined in the clinical laboratory, and in the virus laboratory serum antibody titrations were made to both western equine and St. Louis viruses. In a number of instances tests were made for antibodies to Japanese B encephalitis virus, the latter all with negative results (table 1). In 5 instances in which cases were seen very soon after the onset, throat and nasal washings, after centrifugation at 18,000 revolutions per minute, were tested for the presence of a virus by intracerebral mouse inoculation. These tests were also negative. One of us (W. M. H.) saw practically every patient in consultation, and most of the patients were visited daily or at frequent intervals throughout the period of illness.

In table 1 are presented the results of the serum neutralization tests. It will be noted at a glance that, although this probably represents the most complete series of early and convalescent phase serums yet reported, in but a few instances have the tests made it possible to make an etiologic diagnosis. It certainly indicates that a test on a single convalescent specimen is without value, unless negative.

In each instance the convalescent serum was first tested to determine the presence or absence of antibodies. If positive it was then simultaneously titrated in serial threefold or fivefold dilutions against a dilution of virus representing approximately ten to fifteen LD_{50} intracerebral mouse doses. Most positive serums showed some protection to this amount of either virus in a dilution of 1:125 or 1:625 and occasionally higher. It was found that results obtained when employing the more common method of titrating undiluted serum against serial dilutions of virus were very unreliable in that if repeated at a later date great discrepancies were occasionally noted. Because the factors involved were not understood at the time and therefore could

We were assisted during part of the entomologic survey by Mr. Theodore Aarons and in the laboratory work by Mrs. Anne Thorpe, technician.

From the George Williams Hooper Foundation for Medical Research, University of California, San Francisco, and the Yakima City-County Health Department, Yakima, Wash.

This investigation was carried out under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the University of California and in cooperation with the Washington State Health Department and the U. S. Department of Agriculture, Bureau of Entomology and Plant Quarantine, Division of Insects Affecting Man and Animals. Aided by a grant from the National Foundation for Infantile Paralysis, Inc.

M., and Howitt, Beatrice F.: Epidemiological Aspects of Encephalitis in the Yakima Valley, Washington: Mixed St. Louis and Western Equine Types, Am. J. Hyg. **35**: 163-186 (March) 1942. Hammon, W. M.: *Encephalitis: Eastern and Western Equine and St. Louis Types, as Observed in 1941 in Washington, Arizona, New Mexico and Texas*, J. A. M. A. **121**: 560 564 (Feb. 20) 1943.

not be controlled, the more satisfactory method of serum dilution was substituted. Many minor modifications of the method were tried, and most serums were tested repeatedly.

In 6 instances the titer of antibodies to the western equine virus showed a definite increase. In 2 other cases serologic evidence of an almost incontrovertible nature led to a similar diagnosis of this type infection. These were 2 infants aged 5 and 8 weeks who had antibodies to western equine virus in the one serum specimen obtained, and in neither instance was any antibody present at the same time in the mother's serum.

St. Louis virus antibodies were present in the serums of these same 2 infants and their mothers, but when comparative titrations were made the titer of each infant's serum was much below that of the respective mother. This represents in all probability placentally transmitted St. Louis virus antibody in the infants' serums with titers well below those of the mothers at a period of five to eight weeks after birth.

Five patients developed an increase in antibody titer to the St. Louis virus, but 2 of these also showed an increase in titer for the western equine strain. This

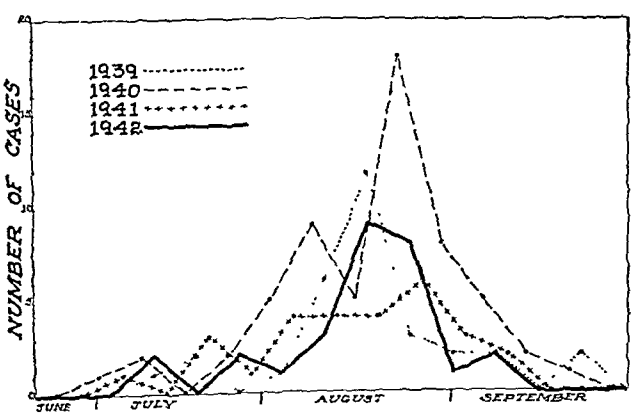

Chart 1.—Cases of encephalitis by weeks, 1939-1942.

increase to both viruses has been reported by us previously and suggestions were made regarding interpretation.[2]

The serums of 10 patients from whom early and late specimens were obtained failed to show an increase of titer to either virus, yet the clinical manifestations, including the spinal fluid findings, were of a nature similar to the others in which the serologic findings were positive (case 13). One of the 10 had antibody to the western equine virus alone, with no change in titer. Six had both western equine and St. Louis antibodies, but the titer of both remained constant. Two had antibodies to St. Louis virus alone, both without change. One had no antibodies to either virus. The last group to be considered includes those from whom only one or no specimen of blood was obtained, or whose serum titration for one virus showed no change and for some reason titration against the other virus was not satisfactorily completed. Results of tests on those from whom at least a single specimen was tested were 2 positive to western equine alone, 2 positive to western equine and not tested for St. Louis, 1 positive to St. Louis alone and 1 to neither. From 1 infant no serum was obtained; thus there were 6 definitely diagnosed western equine infections. 3 to St. Louis virus, 2 possibly infected by both viruses, 10 who probably were not infected by either of these viruses during the illness in question, and 9 who were not adequately studied serologically.

Not 1 case of paralytic poliomyelitis was encountered, and since only 1 central nervous system infection of unknown etiology occurred in a child, we can quite safely eliminate poliomyelitis from further consideration.

The clinical picture varied widely but did not differ essentially from those cases which have been described previously from this area[1] and elsewhere.[3] One very severe case, in an adult, with recovery, has been previously reported in some detail.[4] Four infant cases were diagnosed, aged 11 days, 17 days, 5 weeks and 8 weeks. Despite the fact that infant rates have been high in Manitoba,[5] North Dakota and neighboring states[6] and in California,[7] these are the first seen in the Yakima Valley among 130 cases. Case histories are given for 1 of the youngest infants, for a 9 year old boy with a very severe St. Louis infection and for 2 adults with typical, moderately severe disease manifestations. 1 due to the western equine virus and 1 with unknown etiology:

Case 11.—L. H., a girl, was born July 27 in a Yakima hospital and went home with her mother on July 30 to a poorly screened, mosquito infected home at the edge of the city. There were 8 siblings, all apparently well. The home was adjacent to irrigated pasture and orchard land and was within half a mile of a mill pond. There was a horse with encephalitis in a nearby pasture at about this time. Within 150 yards there were horses, mules, cows, pigs, goats, dogs, cats, rats, mice, chickens, turkeys and ducks. The father recalled killing an engorged mosquito on the infant on August 11. On August 13, fourteen days after coming from the hospital, the infant vomited several times and continued to do so the next two days. Fever was noted on the second day, and the child was taken to a doctor. Convulsions began to occur that day. She was hospitalized on the 16th. The highest recorded temperature, 104.6 F., was on admission at 4 p. m. Convulsions occurred frequently, beginning usually with left sided twitching, progressing slowly to convulsions involving both sides, with extreme deviation of eyes to the right. During and after the convulsions there was cyanosis, and the infant was decidedly spastic at all times. Any attempt to flex the neck or a limb would stimulate another convulsion. The temperature fell slowly to 100 F. on the morning of the 17th but rose to 104.2 F. again that evening, fell to 100.4 F. the following morning and then rose to 102 F. that evening. It was essentially normal that night and remained at a normal level.

On the 17th a lumbar puncture revealed an increased pressure, 478 cells, of which 82 per cent were polymorphonuclears, and an increase in globulin. No organisms were seen in the smear of the centrifuged sediment. Enough fluid was removed to bring the pressure to a normal level. The following day another puncture was made, but blood prevented a suitable count. The pressure was still elevated. At this time the red cell count was 3,860,000 and the leukocyte count 25,800. Convulsions continued without much change until the sixth day of hospitalization. Definite general improvement was then noted, and the formula was voluntarily taken. Treatment in addition to lumbar punc-

ture consisted in repeated parenteral administration of glucose and saline solution, sulfapyridine and gavage feedings. Discharge was on the eleventh hospital day, at which time the infant seemed entirely normal. Blood serum taken August 20 (the seventh day after onset) protected against the western equine virus only when undiluted. Serum on the 27th (the fourteenth day after onset) protected in a dilution of 1:125 at least (highest dilution tested). This serum failed to protect against the St. Louis virus.

CASE 3.—R. S., aged 9, was a normally developed boy from a rural home. There were no other recognized cases in the vicinity and relatively small numbers of mosquitoes were found breeding nearby, but these were principally Culex tarsalis, collected from the chicken houses. His mother knew of only occasional mosquito bites. In the immediate vicinity there were horses, mules, cows, pigs, dogs, cats, rats, mice and large numbers of chickens. On July 26 he first complained of headache and abdominal pain and was found to have a temperature of 100 F. A physician examined him, found a red throat and bilaterally. The bladder was greatly distended, though he had been catheterized a few hours before. His breath was fetid and he was perspiring profusely. Lumbar puncture revealed a pressure of 28 mm. of mercury, and the clear fluid obtained had 164 cells per cubic millimeter, 40 per cent of which were polymorphonuclears. The globulin test was reported normal, and culture was negative. The red cell count was 4,760,000, with 90 per cent hemoglobin, and the white cell count was 11,000, 84 per cent of the leukocytes being polymorphonuclear and 15 per cent lymphocytes. The course of the illness was prolonged and very severe. The temperature ranged for the first two hospital days between 103.9 and 105.2 F. (all rectal). By the sixth hospital day it fell to 101.2 F. and remained between that and 102 F. till about the thirteenth day, then occasionally reached normal but was slightly elevated almost every day for well over a month. He remained comatose and with frequent convulsions until August 3 (the sixth hospital day), when he regained consciousness for a few moments. He remained spastic and required occasional catheterization. Lum-

† Single serum specimen from an infant, mother's serum also positive but titer much higher.
‡ Only one serum specimen tested.

treated him for a sore throat. The following day he was worse, with temperature of 102.4 F. He vomited once and complained of sore throat, dizziness and abdominal pain. The following day the temperature rose to 103.6 F. and he manifested rather pronounced drowsiness. There was, however, no more nausea or vomiting, but abdominal pain continued. The next day, July 29, he was hospitalized because he became uncooperative, irrational and staring and the temperature rose to 104.2 F. Urinary retention and dysarthria also developed. The next day tremors of the hands and jaws developed, the mental confusion first became worse, and by evening he became comatose and generalized convulsions developed. Shortly before coma and convulsions developed he was examined by one of us for the first time. His limbs showed moderate spastic resistance; his speech was garbled and incoherent. His mouth could not be opened. The pupils were regular in shape and size and reacted normally to light. He stared into space, and there was no indication that he saw anything. There was no nystagmus or strabismus. Tremor of the hands was noticeable. The neck was quite rigid, and the back moderately so. There was considerable tension in the hamstrings on both sides. No tendon reflexes could be elicited except the right knee jerk. Abdominal and cremasteric reflexes were absent. There was no Hoffman sign, but there was a positive Babinski reflex bar punctures were made almost daily, showing no change except for an increase in the proportion of lymphocytes. On August 5 and 6 he again regained consciousness temporarily and recognized and spoke to his mother once. However, on the 8th, when the temperature again reached 103.4 F., he began another two days of complete coma. By the 13th he still required tube feeding and spoke only to his parents, and his mental state was obviously still very confused. On the 15th he began to take food voluntarily and showed increased cooperation otherwise. By the end of the month he was able to sit up and was talking glibly, but he lived in a world of imagination. He was last seen that year on September 9. He was still hospitalized, still voiding involuntarily, and was incapable of remembering anything about the present. He recognized persons he knew before his illness and talked intelligently of past events but never learned a new name or face and had no concept of the time of day or memory of any event of the same day or the previous one. He was still running a low grade, daily fever. When seen just recently, two years after the acute phase, a great deal of improvement had occurred but he was far from normal. He can carry on conversation and discuss present or past events quite normally for a short period, but suddenly he will again lapse into fantastic imagination. This change is not apparent except for the incongruity of the facts

he states. He is extremely hyperactive and nervous and occasionally has epileptiform convulsions. He returned to school for a short time and in some subjects did fairly well but at recess time wandered away several times and forgot to return. During the early, acute phase of his illness, sulfonamide drugs were given and they were given repeatedly at later intervals to control exacerbations of urinary tract infection. Blood serum was taken the third, fifteenth and thirty-third days after onset. All serums failed to protect against the western equine virus and the Japanese B virus, but an increase of titer was detected to the St. Louis virus, the final titer reaching 1 : 243.

CASE 13.—C. S., a man aged 49, a farmer who had lived twenty years in the Yakima Valley, his home and farm being near the southern end of the valley, on August 18, in connection with what he thought was a cold, developed a severe headache with nausea after a few hours of general malaise and coryza. He continued to work for two more days with the headache becoming progressively worse; then he vomited several times, went to bed and called a physician. After two days in bed at home he became so much worse that the physician insisted on hospitalization. On August 21, at the time of hospital admission, he was found to have a temperature of 104 F., he was flushed, the face was edematous and he was bewildered, speaking thickly and slowly with great difficulty, sometimes irrationally. He had a mild tremor of the mandible when attempting to speak. He was severely dehydrated, his breath was foul and he was sweating profusely. His pupils were regular in shape and equal in size but quite contracted even in a darkened room. Vision appeared to be normal and there was no nystagmus or strabismus. The throat was moderately injected. The tongue had a definite but fine tremor. The neck was moderately stiff and the hamstrings were tense, but the back showed almost normal flexion. All extremities were very slightly spastic. The biceps and knee jerks were present and equal, but other tendon reflexes could not be elicited. Hoffman and Babinski reactions were not elicited. Abdominal reflexes were absent and the left cremasteric could not be demonstrated. Neither scrotum contracted after pinching. The spinal fluid was clear but contained 177 cells, of which 16 per cent were polymorphonuclears. The globulin was increased. The following day, after adequate fluids had been given, the red blood cell count was 3,990,000, the hemoglobin 79 per cent and the leukocyte count 17,600, 78 per cent of the leukocytes being polymorphonuclears. During the next three days, though the temperature gradually fell to a maximum of 101.4 F., he progressively developed more severe tremors of the tongue, chin, arms and legs. However, he felt better, the headache and general malaise having decreased. His mentality also cleared during these three days. By August 28, the seventh hospital day, his reflexes were all present and normal, the edema had left the face, he was eating well and the temperature was normal. However, the tremors were still very noticeable. His only drug treatment was sulfathiazole during the acute phase as a prophylaxis against secondary bacterial invaders. He was discharged on September 13, still slightly tremorous and very easily fatigued. Serum taken on the fifth day of illness protected against the western equine virus only when undiluted, but on the twenty-fifth day it protected in a dilution of 1 : 125. Neither serum protected against the St. Louis virus.

CASE 16.—A. B., a man aged 48, an orchard laborer, a resident of the valley for twelve years, living just outside a small midvalley town in a typical rural setting, with mosquitoes, chickens and other animals. On August 21 he developed a severe headache, then nausea, vomiting, dizziness, abdominal pain and feverishness later in the day. He also complained of severe pain in the legs and back. The following day he became very drowsy and noted photophobia together with intensification of other symptoms. Ou August 23 (the second day of illness) he was hospitalized. The maximum recorded temperature that day was 101.4 F. He appeared very drowsy and toxic, and his face was bloated. His pupils were regular in size and reacted to light but were abnormally small. Otherwise his eyes were normal. There was no tremor of the tongue or hands and the speech was normal, though slow. The neck was moderately rigid and the hamstrings were tight. The abdomen was slightly distended. All the limbs seemed slightly spastic. Biceps tendon and knee jerks were normal, but other tendon reflexes could not be elicited. There was a positive Babinski reaction on the left. Both abdominal reflexes were absent and the scrotum failed to contract on pinching, though both cremasteric reflexes were normal. The spinal fluid was clear, with 48 cells per cubic millimeter. There were 38 per cent polymorphonuclears, 50 per cent. lymphocytes and 12 per cent large mononuclears. On the following day the patient was slightly worse, with the temperature up to 103.6 F. The next day he had a chill, became quite restless, tremors of the mandible and the tongue appeared and his headache was much more severe. There was a partially sustained clonus of both legs. The next day (August 26) he groaned constantly with headache and cared about nothing else. A lumbar puncture showed a slight increase in pressure and 60 cells, 96 per cent lymphocytes and 4 per cent large mononuclear. The headache was partially relieved following the tap. The maximum temperature was 101 F. He was much improved the next day, the temperature was down and all reflexes were normal. Improvement was constant and he was discharged from the hospital on September 9, seventeen days after admission. Serum taken on the second and twelfth days after onset contained a high titer of antibodies to both western equine and St. Louis virus, but no change of titer could be demonstrated It must be supposed that the patient had serologic immunity to both of these viruses at the onset and was probably infected by another one which produced a similar clinical disease.

There were but 2 fatal cases in this outbreak, making a case fatality rate of 7.2 per cent. In 1940 and 1941 the rates were 22.4 per cent and 11.5 per cent respectively. Experience in treating the severe cases probably contributed to this reduced fatality. In 1 of the 2 fatal cases of 1942 death occurred in a nursing home on the fourth day of illness, a few hours after "half a cup" of spinal fluid was drained out. There was not enough information obtained to draw any definite conclusions as to the severity of the illness or the immediate cause of death. The other fatality was of a woman aged 70 who developed pulmonary complications on the fourth day while on inadequate sulfonamide dosage. She obviously needed continual special nursing care and it was requested, but owing to inability to obtain special nurses at the county hospital because of inadequate local supply she did not receive anywhere near adequate care and died of bronchopneumonia about forty-eight hours later. There were 6 other patients over 60 years of age who had severe disease but did recover, owing in a large part to excellent medical and nursing care. All but 1 had sulfonamides during the acute phase, probably preventing in some instances pulmonary and urinary complications.[4] Tube feeding, parenteral fluids, frequent turning and other symptomatic treatment contributed greatly. This consultant (W. M. H.) noted a pronounced improvement in the care of these cases during the three annual epidemics. The case fatality rate changes, though possibly not significant statistically, are at least highly suggestive.

Two other cases merit mention because of special interest. This consultant was called to see 1 patient suspected of having a virus encephalitis because of temporary coma, restlessness and delirium with high fever. Spinal fluid findings were negative and the temperature curve suggested malaria. The first blood smear made contained large numbers of Plasmodium falciparum parasites. This was an autochthonous case of cerebral malaria, a rather infrequent infection in the Yakima Valley. In 1 proved case of western equine infection the first symptoms appeared just after he had given blood for a transfusion. The recipient did not develop any symptoms of encephalitis.

EPIDEMIOLOGY

The age distribution of cases is presented in tables 1 and 2. It will be noted that the distribution indicates either an increased exposure or increased susceptibility at the extremes of life. The mean age is 36 years, as compared with 46 for 1940 and 25 for 1941.

The sex distribution, table 2, assists little in the interpretation of the age incidence. In most large outbreaks of the western equine infection the sex distribution of very old and very young has been equal and males predominated heavily only in the adult and "teen" age working group. Here there are 21 males and 7 females, with little difference in proportion of any age group except infancy. This discrepancy may be due entirely to chance distribution in these small numbers.

TABLE 2.—*Cases of Encephalitis by Age and Sex*

Age in Years	Number of Cases		
	Male	Female	Total
Under 1	2	2	4
1 - 4	1	0	1
5 - 9	1	0	1
10 - 14	1	2	3
15 - 19	0	0	0
20 - 29	2	0	2
30 - 39	2	0	2
40 - 49	4	1	5
50 - 59	1	1	2
60 plus	6	1	7
Unknown	1	0	1
Total	21	7	28

The geographic distribution varies but little from that observed previously. Eight patients lived in an urban area, 10 suburban and 10 rural. Only in 2 instances did the place of work differ from that of residence; 1 rural resident worked in a suburban area, and 1 suburban resident worked in the city of Yakima. Since the urban population represents about one third that of the whole county, there is little difference in the rates between urban and the combined suburban and rural rates. This is comparable to the findings in 1940, when rates were 57.5 and 62.7 per hundred thousand respectively. Nevertheless, when cases are plotted on a map the urban distribution is shown to be largely at the periphery of the city, where conditions in regard to domestic fowl are suburban or rural in nature.

TABLE 3.—*Cases of Encephalitis by Time of Onset*

Time in Weeks	Cases
July 10 to 16	2
17 to 23	0
24 to 30	2
31 to August 6	1
August 7 to 13	3
14 to 20	9
21 to 27	8
28 to September 3	1
September 4 to 10	2
Total	28

Seasonal distribution, as previously mentioned, and shown in chart 1 and table 3, is almost identical to that of previous years. The peak occurred during the middle and latter part of August. Quantitative mosquito studies made by Mr. W. W. Yates of the Portland office of the Bureau of Entomology and Plant Quarantine, Division of Insects Affecting Man and Animals, U. S. Department of Agriculture (under the direction of Mr. C. M. Gjullin), by using five New Jersey type light traps, showed that the activity of Culex tarsalis again correlated well with the epidemic curve[8] (chart 2). The period of greatest activity of several species, including Culex tarsalis, just preceded the peak in onset dates of human cases, a period representing probably the incubation period in man and mosquito.

MOSQUITO AND "RESERVOIR"[9] FOWL STUDIES

During the preceding year five strains of western equine virus and three of St. Louis virus were isolated from 4,655 Culex tarsalis mosquitoes tested from this area.[10] Since no virus was isolated from any other arthropod tested the previous year, the survey was limited to mosquitoes in 1942. During July and August a total of 24,751 mosquitoes, including nine species, were collected and tested for virus content, yielding forty-nine strains of virus. Of these mosquitoes 9,466 were Culex tarsalis. Results of the tests are presented in table 4. A total of forty-five viruses was isolated from this species, forty-one western equine and four St. Louis strains. Thus, in Culex tarsalis an infection rate was demonstrated of at least 1 in each 210 collected, as compared to 1 in each 386 found the preceding year. The role of Culex tarsalis as a natural vector of these viruses in the Yakima Valley is thus amply confirmed. In addition to the isolations of virus from Culex tarsalis, one strain each of western equine and St. Louis virus was isolated from Culex pipiens. Strains of western equine virus were isolated from Culiseta inornata and Anopheles maculipennis freeborni. No virus was isolated from 7,503 Aedes mosquitoes tested.

TABLE 4.—*Viruses Isolated from Mosquitoes Caught in Summer*

Mosquito Species	Number Tested	Viruses Isolated		
		Western Equine	St. Louis	Total
Culex tarsalis	9,466	41	4	45
Culex pipiens	967	1	1	2
	1,950	1	0	1
	4,496	1	0	1
	4,866	0	0	0
Aedes vexans	2,513	0	0	0
	124	0	0	0
	397	0	0	0
	62	0	0	0
Totals	24,751	44	5	49

An interpretation of the significance of these virus isolations by consideration of the vector abilities of the different species concerned leads to interesting conclusions. Culex tarsalis has been demonstrated to be an efficient vector of both western equine[11] and St. Louis viruses.[12] It feeds predominantly on fowl

8. Hammon, W. M.; Reeves, W. C.; Brookman, B., and Gjullin, C. M.: Mosquitoes and Encephalitis in the Yakima Valley, Washington: V. Summary of Case Against Culex Tarsalis Coquillett as a Vector of the St. Louis and Western Equine Viruses, J. Infect. Dis. **70**: 278-283 (May-June) 1942.

9. Reservoir animal is used here and elsewhere in this paper when in quotations in a restricted sense. All known vertebrate sources of these viruses are infectious for only a short time and thus are not *reservoirs* in the usual sense of an animal having a latent or chronic infection which may serve as a source of infection over a long period. No such a true reservoir for these viruses is known as yet. Such a reservoir, if it exists, might be vertebrate or invertebrate.

and occasionally on mammals. It becomes readily infected by feeding on fowls at a time when virus is present in the blood, and specimens thus infected become, in turn, infective by their bite after a suitable extrinsic incubation time at high temperatures.[13] Thus, it would appear that this species is an important vector of both western equine and St. Louis viruses.

Culex pipiens was found infected this year with St. Louis and western equine viruses. This species also acts as a laboratory vector of St. Louis virus [14] and thus can now be considered an established natural vector. However, in all laboratory tests this species has lost every detectable trace of western equine virus in twenty-four hours.[15] It would appear that the recovery of western equine virus from a mosquito of this species, in nature, was an instance of finding a specimen recently engorged on an infected "reservoir" animal, and the virus would probably have disappeared within a few more hours.

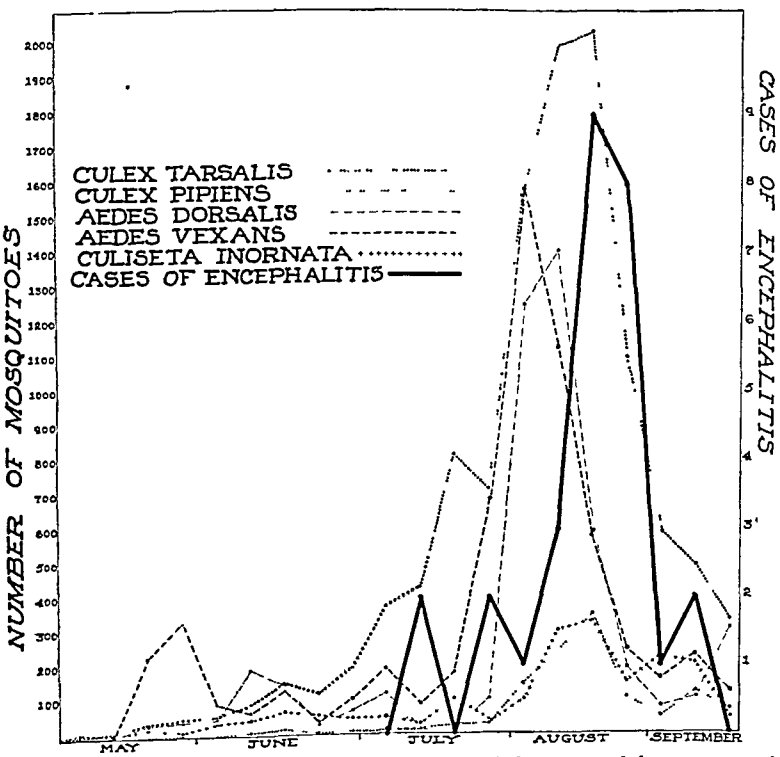

Chart 2.—Principal species of mosquitoes caught in light traps and human cases of encephalitis, by weeks.

Culiseta inornata, found infected with western equine virus, is capable of acting as a vector in the laboratory [11] and if present in large numbers might serve as a vector of importance.

Anopheles maculipennis freeborni, found infected with western equine virus, has been demonstrated to lose all detectable virus within twenty-four hours.[11] Thus, this species, like Culex pipiens, was infected in nature but apparently would not have become infectious by its bite.

Culex pipiens (St. Louis) and Culiseta inornata (western equine), the potential vectors other than Culex tarsalis which were found infected, were present in comparatively small numbers (chart 2) and could be of but small importance.

No virus other than western equine and St. Louis types was isolated from any source during the investigations.

During the survey of the previous year (1941) a small scale study was made of the feeding habits of Culex tarsalis.[16] This study was made by application of the precipitin test technic and by direct observation. This phase of the problem was greatly enlarged in the 1942 study, to throw more light on probable vertebrate reservoirs and in an attempt to discover why excellent laboratory vectors like Aedes were not found infected A large series of blood engorged specimens, collected in domestic habitats, were tested by means of the precipitin method to determine the relative proportions which fed on domestic animal "reservoirs" of these infections and on man.[17] At the same time, hand collections were made on the horse, cow and man to determine which of the various mosquito species fed on these hosts. It was found that Culex tarsalis, the species best fitting the epidemiologic picture as a mosquito vector of encephalitis in this area, fed frequently on birds (45.7 per cent of all tested) and included most of the common domestic animals in its feeding range. The feeding habits of this species alone could result in the incidence of encephalitis antibodies demonstrated in domestic animals and man by means of the neutralization test.

Other species which were rarely or never found infected in nature appeared to be those which fed almost exclusively on large mammals (Aedes dorsalis, 96.6 per cent) which, if all like the horse, have low titers of virus in the blood, probably too low to permit infection of the mosquito.

Culex pipiens was the exception, as it fed almost exclusively on fowl. This species can now be considered a natural vector of St. Louis virus, probably important in the St. Louis area but, because of small numbers, not important in the Yakima Valley.

The results of the precipitin tests, and the repeated isolations of virus from Culex tarsalis, together with previous evidence from a serologic survey [18] give strong support to the probability that domestic fowl are an important "reservoir" of infection in the Yakima Valley. In the laboratory, the blood of domestic fowl (chickens) has been shown to serve as an excellent source of virus to infect mosquitoes

In order to determine, if possible, whether encephalitis viruses are carried through the winter by hiber-

nating mosquitoes, 5,973 such mosquitoes were collected in the Yakima Valley during January 1943 while snow was on the ground and the temperatures ranged down to minus 15 F. All tests for virus were negative. Only 18 Culex tarsalis could be found, but of Culex pipiens there were 4,789, of Anopheles 1,161. Culex pipiens and Anopheles undoubtedly winter predominantly as adults, but although Culex tarsalis has been reported to do so, it seems quite possible from our observations that some other mechanism of overwintering may be more important in this area. This may have an important bearing on the epidemiology of the disease. All our attempts so far, however, to obtain evidence of transovarian infection in Culex tarsalis of both viruses have been entirely negative.

At the end of the season to determine roughly infection rates of the two viruses in chickens, which we consider very important sources of mosquito infection, serum was drawn from 20 chickens from the spring hatch of 1942. Six definitely had antibodies to the western equine virus, and 5 had low titers in a questionable range. To the St. Louis virus only 2 had any protective power, and these fell in the questionable range. This proportion is comparable to the infection rates found in mosquitoes, 44 western equine, 5 St. Louis, indicating considerable preponderance of the western equine virus during the season in question.

SUMMARY

1. In the fourth and last of a series of annual epidemics of encephalitis in the Yakima Valley, diagnosis was accepted in 28 cases. Titration of antibodies in acute and convalescent phase serums established the diagnosis of western equine or St. Louis encephalitis in 11, 10 clinically similar cases failed to develop an increase in titer to either and so are attributed to a hypothetical third virus, and the others were not so completely studied serologically. Six serums were tested for antibodies to Japanese B virus, with negative results.

2. Maternal transmission of St. Louis virus antibody to 2 infants occurred.

3. The case fatality rate was only 7.2 per cent. The decrease from previous years (22.4 and 11.5 per cent) is attributed in part to therapy and care.

4. The occurrence of a case of autochthonous cerebral falciparum malaria introduced an additional problem in differential diagnosis.

5. Transfusion on the day of onset from 1 patient failed to produce encephalitis in the recipient.

6. Activity of Culex tarsalis mosquitoes, as indicated by light trap collections, correlated with the epidemic wave.

7. Forty-nine strains of virus were isolated from four species of mosquitoes. From Culex tarsalis were isolated forty-one strains of western equine virus, and four strains of St. Louis virus. Infection rates in Culex tarsalis were at least as high as 1 in 210.

8. Culex pipiens was found infected with both viruses but will transmit only the St. Louis strain. It is now a proved natural vector of St. Louis virus.

9. Culiseta inornata found infected with western equine virus was demonstrated to be capable of transmitting it and so becomes a proved natural vector of the western equine virus.

10. In mosquito collections made during the winter, no virus was found. It was observed that few Culex tarsalis adults, if any, survive the severe winter in the Yakima Valley.

11. Antibody studies in the 1942 season's chickens indicated that 30 to 50 per cent had been infected with western equine virus but very few with St. Louis virus. This correlates well with the proportion of the two viruses isolated from mosquitoes.

PSYCHOSOMATIC ASPECTS OF FILARIASIS

PRESENT DAY EVALUATION

LIEUTENANT COMMANDER MEYER A. ZELIGS (MC), U.S.N.R.

Knowledge of the clinical characteristics of filariasis among Marines who have returned from the South Pacific has taken a broad step forward during the past year. A sounder appreciation of the later symptomatology and clinical course of this exotic disease, together with a continued opportunity to study its psychologic aspects, has made it possible to envisage more definitely the ultimate prognosis of such cases and has clarified many of the misconceptions which unfortunately have arisen in regard to this heretofore almost unheard of condition. This advance in medical understanding has been brought about by careful study and observation of a large group of Marines who were returned from the South Pacific because of filariasis. This report represents but a small part of the clinical and rehabilitative work which is now going on at the Marine Barracks at Klamath Falls, Ore.

The need for such a center as the Marine Barracks at Klamath Falls developed after the return to the United States of large numbers of Marines with filariasis for whom no definitive plan of treatment or observation had been worked out and in regard to whom only meager scientific data were available. Knowledge of this rather obscure tropical disease in the white man had thus far been limited to short term studies by a few observers working under a diversity of environmental conditions in the field and in the United States. The problem of the ultimate disposition of these men by the military, based on statistically sound group observations, had yet to be worked out. There was thus an important need for the development of a site and program for the study of these individuals under properly controlled conditions. And so, early in 1943, in a joint undertaking by the United States Marine Corps and the Bureau of Medicine and Surgery of the U. S. Navy, the Marine Barracks at Klamath Falls was conceived and established. Its purpose was to be twofold:

(*a*) The general rehabilitation of Marines returned from overseas with filariasis or malaria (or both).

(*b*) The careful study and investigation of the clinical, therapeutic, laboratory, animal experimental and psychologic aspects of these two diseases.

The successful accomplishment of such a project necessitated the highest degree of integration between the administrative and medical departments. A well controlled program which included a graded type of physical activity, vocational and educational courses, military training and recreational activities was inaugurated, all of which was fitted into an organized schedule

From the U. S. Marine Barracks, Klamath Falls, Ore.
This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

in a background of continuous medical observation. The untoward and actually deteriorating effects of improper rest and inactivity on individuals with chronic, nonincapacitating disease such as filariasis are now well understood by all who have dealt with such problems, and circumvention of this long existent therapeutic pitfall was one of the primary considerations in shaping the new rehabilitative ideology of this station. An aura of activity and vigor was to innovate the atmosphere before any clinical observations of real worth could be recorded. It will be noted that I have referred to the Klamath Falls Station as a "Marine Barracks" and not as a recuperative or convalescent center. This I have done advisedly and deliberately, for it was our purpose from the outset to establish a post which would function in a combined military, vocational and educational capacity and would in no sense resemble or be regarded as a hospital. The men at the station were not referred to as "patients"; they were officially carried on the Marine Corps roster on a full duty status, unless specifically excepted because of some concurrent disabling condition. Each man enjoyed the various benefits and privileges which are generally forthcoming to every one while on active duty (such as eligibility for promotions, awards, furloughs and living off the post if married).

All Marines sent to duty at the barracks at Klamath Falls had signs of active filariasis or a history of having had filariasis during the past two years (or malaria). Those just returned from overseas, following an initial physical examination which was performed immediately after their arrival, were allowed a thirty day (overseas) furlough and on their return from leave were again examined and classified as to the type of duty which they were to perform. Thus all men sent to Klamath Falls were immediately placed on a prepared program for the duration of their stay unless they had to be hospitalized. This was to be an active duty station in its fullest sense, despite the fact that almost 80 per cent of our complement had come as former patients from the various naval hospitals and convalescent centers. The medical department functioned in the background of this setting and as an integral part of the station. It comprised a staff of medical specialists, picked laboratory research workers and technicians, nurses and corpsmen. The hospital wards and laboratories were amply equipped with all the medical and technical facilities necessary for comprehensive treatment and research.

During the formative months of the station's development, the transition for many of the men from their former convalescent or hospital routine to one of activity was accompanied by considerable difficulty. Such individuals had become physiologically and psychologically weakened as the result of months of sedentary or convalescent existence and for a considerable time were unable to meet the physical demands which this active routine required. The psychosomatic reactions to this change lasted for a few months, during which time the daily sick call was full to overflowing (at one time reaching as high as 12 per cent of the total personnel) with complaints of fatigue, fear of collapse and sundry inabilities to perform the seemingly arduous duty now required of them. Symptoms referable to sites of old injuries or disease which had been quiescent or healed for many months were psychologically brought to light and reactivated. Among these were headaches, backache, diverse gastrointestinal complaints (especially vomiting) and a host of other psychosomatic disturbances. As the training program developed, however, and the intractably psychoneurotic and other inadequate individuals were separated out, the general attitude and group morale improved dramatically and the men became desirous of completing the prescribed three months training period. In the event of reactivations, they were observed for a longer period.

For purpose of this particular study, the total complement of the station was divided into two main groups:

(*a*) Individuals with signs or history of filariasis recently returned from overseas.

(*b*) Those similarly affected but who had been evacuated to the United States six to twelve months previously and who had been "convalescing" at various naval hospitals throughout the country.

A comparative study of these two groups was undertaken, and the attitude of each individual in the group toward his symptoms was determined by careful psychiatric appraisal. Over 500 such interviews were conducted, the examiner attempting primarily to discover the extent to which the subject's mental attitude colored or affected his ability to perform active duty. A special attempt was thus made to elicit whether individuals with filariasis, after six to twelve months in the United States as convalescents or on some type of limited duty, had developed any particular or fixed attitudes in relation to their symptoms and, if so, to what degree this acquired neurotic behavior was manifest. The element of secondary gain, which invariably arises after such a neurotic pattern has been achieved, was measured by the degree of insistence for light or limited duty. In addition to the foregoing, and of essential interest in this study, was an evaluation of the degree of anxiety in these men as evidenced by expressed fear of sterility, sexual impotence and loss of libido. Following is a summary of the impressions which were formed as a result of these interviews:

1. Individuals who had been hospitalized for at least a month (or longer) were, as a group, less capable of performing active duty as compared with those who had had similar symptoms but who had not been hospitalized for more than a few days after their return to the United States. Following treatment of presenting complaints, reassurance and the inauguration of an appropriate training and vocational program which allowed expression of natural aptitudes and interests, individuals in this group soon adapted themselves to the required active routine. In general, it was found that the longer the preceding period of inactivity, the more difficult and protracted was the return to active duty.

2. Individuals recently out of combat and exhibiting classic symptoms of war neurosis or combat fatigue (battle nightmares, startle reactions, increased tension, personality change) were but little concerned about their filarial symptoms and were especially desirous of overcoming their acute nervous disturbances.

3. Individuals whose past history showed evidence of psychoneurotic behavior before they developed filariasis almost invariably utilized their filarial symptoms to help solve preexisting neurotic needs or conflicts. Exaggeration of complaints and pronounced somatic-mindedness, in the face of negative physical findings, was especially prominent in this group. Generalized aching of muscles and joints and easy fatigability were the most common features in this group.

Demonstrable signs of filarial activity was found in less than 4 per cent of all individuals and in all cases after one or more reactivations no further incapacitating

sequelae occurred. In an earlier analysis of this same group Haviland [1] reported the degree of involvement found at the time of the initial "screening" examination as presented in table 1. It will be seen that 91 per cent of men were sufficiently free from symptoms so as not to require medical attention. Of this group 40 per cent showed "mild" involvement, which usually amounted to transient aching or swelling of an extremity or of the spermatic cord following moderate or heavy physical exertion. In many cases the complaint was entirely subjective (aching, but no evidence of swelling or redness) and as the patient became physically and psychologically adapted to his activity these symptoms disappeared. With these facts in mind, let us now compare the rate of attendance at the "filariasis clinic" during its first two months with the next four months (chart 1). One sees a progressive decline in the percentage of the station complement attending the "filariasis clinic" as the period of training ensued. It is to be emphasized, furthermore, that this decline in clinic attendance occurred during the very same months in which the total filarial complement of the station

TABLE 1.—*Examining Physician's Evaluation at Time of "Screening Examination"*

(Taken from Haviland)

Physician's Evaluation	Men Involved (%)
[illegible]	51.0
[illegible]	40.0
[illegible]	9.0
Severe involvement	0.2

TABLE 2.—*Pregnancies and Births Among Wives of Marines with a History or Signs of Filariasis*

Marital Status	Cases	Pregnancies or Births	Disturbed Sexuality (Psychic Impotence, Fear of Sterility, and So On)
Married	249	45	10
Single	657	0	17
Total cases	906	45	27

was steadily increasing as the result of the continued arrival of new cases. Despite the constant increase in the filarial complement, one sees a progressive decline in the total percentage of men attending the "filariasis clinic" as the training program continued.

Chart 2 shows the total filarial complement of the station by months. At the present time the approximate attendance at this clinic is about 1 per cent of the station's total filarial complement (chart 1, January 1945). This trend is of real significance and is emphasized as one of the essential points of this report, for it categorically summarizes the beneficial effects which took place in these men following proper physical conditioning and the removal of unfounded psychogenic fears and apprehensions concerning the outcome of this disease. Especially prevalent among the latter was the fear of sterility and other evidences of disturbed psychosexuality.

The data given in table 2 show the incidence of pregnancies and births among wives of Marines returned to the United States with a history or signs of filariasis and were obtained during the last weeks of the three to four month training period ("final screening examination") which was done preparatory to each man's transfer to another station. This table also shows the incidence of disturbed sexuality, from any cause, among the single and married Marines under observation for filariasis. It is evident that there has been no interference with procreation (18 per cent of wives were pregnant or gave birth) and the incidence

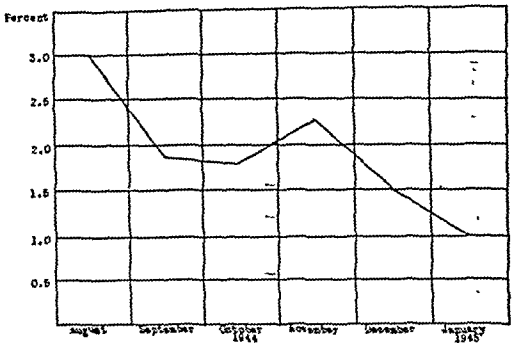

Chart 1.—Percentage of total complement of station (with filariasis) attending "filariasis clinic."

of disturbed sexuality of psychogenic origin was well within the range of normality (2.8 per cent) for any group of individuals.

COMMENT

It appears thus, from the data presented, that the disease filariasis in a nonendemic area has a definite tendency to burn itself out after one or more reactivations. The precise mechanism for this is still under dispute by pathologists, though it is felt by most investigators [2] that the symptoms of reactivation (characterized clinically by mild fever, localized redness and swelling, retrograde lymphangitis and regional lymphadenitis) are caused by the ultimate development of an adult worm, which, having grown to its full size, creates an obstructive, inflammatory reaction in the lymphatic channels in which it is lodged and then dies and disintegrates, the latter process accounting for the acute clinical signs. Whatever the exact pathologic process may be, whether it is an obstructive one or a local allergic phenomenon or both, has yet to be determined

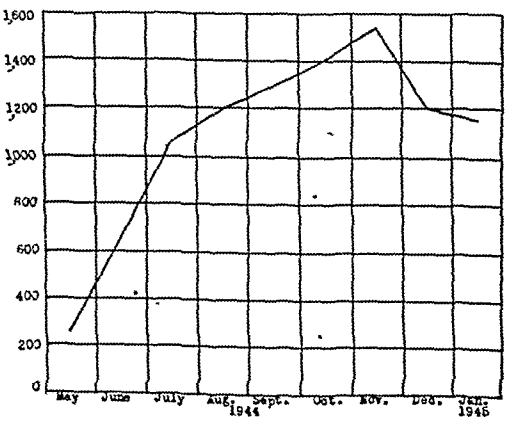

Chart 2.—Total filarial complement of station by months.

accurately. The essential point in regard to the problem under discussion is that in individuals so affected, when removed from endemic areas, the disease runs a self-limited course and soon dies out. This categorical statement is one which until now could not be unequivocally made, because of the lack of adequate clinical data which are now at hand.

2. Zuckerman, S. S., and Hibbard, J. S.: Clinicopathologic Study of Early Filariasis, U. S. Nav. M. Bull. 44:27-36 (Jan.) 1945.

Factual knowledge, such as this, has proved of immense importance in the therapeutic handling of these and more recently arrived cases. Just a year ago Rome and Fogel,[3] in a then timely article, discussed the keen and almost universal anxiety which was seen to be associated with this disease soon after its inception. This state of apprehension was brought about by a combination of several reasons: First, the admitted lack of knowledge by medical officers at that time concerning the cause and possible sequelae of this disease when they were first faced with it in such large numbers in the Samoan area and, secondly, the fact that in about 50 per cent of cases the genitals were initially involved, this anatomic site being especially prone to produce anxiety due to fear of subsequent impairment of sexual function. This understandable emotional overlay was present at the onset in almost all men afflicted, genitally or otherwise, and continued observance and psychologic identification with native Samoans (in whom the incidence of obvious "mumu" or gross elephantiasis in some villages ran as high as 85 per cent) served to enhance and maintain the unwholesome state of mind. In many of the more suggestible, imaginative and psychologically susceptible ones, as Rome and Fogel go on to point out, actual mental depression occurred. In others, psychic impotence and profound fear of sterility developed after their return to the United States. Such psychosomatic manifestations no longer obtain, however, and this brings us to the present day evaluation of this aspect of the problem. From a clinical and statistical review of the group of patients in this study it can now safely be said that the initial anxiety concerning the outcome of this disease, such as impairment of sexual function and the development of elephantiasis of limbs or scrotum, is no longer present. Only in previously psychoneurotic or constitutionally inadequate individuals is there still evidence of such worries and fears. It is to be further emphasized that the regimen which was used to overcome this state of apprehension included a program of prophylactic psychiatry which was soon replaced by the subject's own appreciation, in terms of actual performance, that his physical and sexual prowess were not impaired. Rome and Fogel emphasized the importance of disseminating encouraging propaganda regarding the future course of this disease. They pointed out that this was an essential factor in helping to prevent the spread of false and exaggerated notions of the sequelae of this condition. This is indeed important, but one must remember also that such "psychologic inoculation" is but temporary and "passive" and will soon become attenuated unless it is fortified and substantiated by the patient's own proof that his sexual performance and virility have remained intact. Normal sexuality, as demonstrated by months of maintained potency and virility and evidenced among the married men by a normal rate of pregnancies and births, has served as the final and indisputable proof. This was the final blow which served to dispel any remaining apprehension in this regard.

CONCLUSIONS

The following conclusions concerning the course, prognosis and psychosomatic features of patients with filariasis derive from this study:

1. Following removal of individuals afflicted with early signs of filariasis from the endemic area, the disease has been shown to run a self-limited course and, after one or more clinical reactivations, burns out.

2. The rehabilitation and restoration to full duty of individuals with signs or a history of filariasis is in a large measure dependent on a combined program of military, vocational, educational and medical training and supervision, this being of especial significance in the handling of men previously weakened by prescribed inactivity.

3. No demonstrable impairment of sexual function, either libidinous or procreative, has resulted from this disease.

4. Severe or incapacitating sequelae have thus far occurred in only 0.2 per cent of persons with filariasis.

5. The clinical, military and psychologic import of this wouldbe problem should, within another year or so, have entirely disappeared.

FILARIASIS

EARLY CLINICAL MANIFESTATIONS

AN ANALYSIS OF THIRTY-FIVE CASES

CAPTAIN WILLIAM SAPHIR
MEDICAL CORPS, ARMY OF THE UNITED STATES

Filariasis is a tropical disease endemic in many parts of the world that are now inhabited by American troops. In its importance among mosquito borne diseases it looms second only to malaria. However, unlike malaria, the importance of filariasis as a military medical problem has not been fully evaluated as yet because of its long incubation period, estimated to last as long as two years. It is only recently that American military personnel stationed in endemic areas have reached the end of this incubation period. A proper evaluation of the problem should therefore soon become apparent.

Filariasis, moreover, may well constitute an important future civilian medical problem. Theoretically, any soldier returning from an endemic area may develop filariasis two years hence when he may well have returned to civilian life. It becomes obvious, therefore, that physicians throughout the United States may be called on to recognize early manifestations of filariasis.

This report is based on the observation of 35 cases admitted to a station hospital of the South Pacific Forward Area and presenting a symptom complex suggestive of early filariasis.

It is readily conceded that the final proof for the diagnosis, the demonstration of Filaria bancrofti or its larvae, was missing in all cases. Repeated thick blood smears taken at different hours of the day and night failed constantly to reveal microfilariae. This observation is in accord with many attempts in large numbers of similar cases.[1]

A great deal of work is being done at present to devise laboratory methods helpful in the diagnosis of early filariasis. Such tests as skin tests and immunity reactions either are in the experimental stage or have failed to prove their usefulness.[2] It appears, therefore,

important to depend on a clinical picture which should be sufficiently characteristic to permit a diagnosis of early filariasis.

Current textbooks [3] offer a great deal of information on the later stages of the disease, such as the febrile filarial attacks and the final chronic stage, the elephantoid type of the disease. However, information as to the early stage of the disease, immediately following the incubation period, is scanty. It is this stage which at this time presents a pressing problem for medical officers serving in tropical and endemic areas. Such a stage of early filarial disease has been described as a latent symptomless period which follows the incubation period and which may last for several years or even throughout life. There are said to be typically no manifest symptoms, although local tissue alterations around the adult worms may be in progress.[4]

My observations would bear out the fact that early filarial disease is not as symptomless as formerly believed and that a rather well defined clinical picture presents itself, sufficiently typical to suggest the presence of the disease. The characteristic salient features of 35 cases are herewith described.

CLINICAL HISTORY

The clinical history was significant in many respects. All soldiers came from an area known to be heavily infested with Filaria. They were exposed to day and night biting mosquitoes. At times they were assigned to night duty, such as night guard duty, night repair crews and unloading ships.

Under the assumption that the time of their arrival at the endemic area was identical with the time of exposure, the incubation time in this series of cases lasted from three to six months. After this period symptoms became noticeable. All patients were hospitalized from one to three months after onset of symptoms. The clinical syndrome described herein would represent, therefore, a stage of filariasis which appears four to nine months following exposure.

The disease started slowly and progressed gradually with intermissions. The most frequently described early symptom was a feeling of numbness or weakness in a leg or an arm. Frequently the affected extremity would "fall asleep," particularly at night, disturbing the patient's sleep. This was shortly followed by an aching sensation in one or more extremities, particularly after heavy work. Gradually the ache developed into a frank pain which was keenly felt during the rest period immediately following heavy exertion. The pain usually originated in the axilla or groin and it was then that the men discovered the presence of axillary or inguinal lymphadenopathy.

As time progressed any mild exertion such as a brisk walk would elicit pain in the affected parts. Eventually a certain periodicity became unmistakable. With or without preceding exertion, periodically recurring pains around the axilla, arms, groins, thighs and scrotal regions were described, occasionally accompanied by visible swellings, particularly around the groin and scrotal regions. The duration of these periodic attacks was described as lasting from a few hours to several days, followed by periods of days or weeks of well being. Nocturnal occurrence of the attacks was frequently observed, and even in the quiet periods of intermission nocturnal pains of various degree were noted. This was especially true of nightly recurring testicular pains. Such nocturnal orchiodynia was experienced so commonly that it constituted an important part of the patient's history. Finally the patients became aware of the constant presence of palpable nodes, notably around the groins and scrotal regions, although periodic changes in the degree of such enlargements were common.

Such a history usually covered a period of from four weeks to three months prior to hospital admission. None of the patients gave a history as to involvement of constitutional signs or symptoms such as general malaise, headaches or loss of weight, strength or appetite. In fact, general well being was usually emphasized. Only 1 patient gave a history of fever during attacks of pain, and this was verified by hospital observation.

PHYSICAL FINDINGS

Physical examination disclosed all patients in good general condition. There was no evidence of weight loss, debility or anemia. Cardiovascular, respiratory and gastrointestinal systems were found normal findings were strictly confined to the lymphatic and genital system.

Involvement of the lymphatic apparatus was characterized by a more or less generalized lymphadenopathy, which was present in all of the 35 cases. The lymphadenopathy consisted of multiple slightly tender, firm well separated nodes of from pea to walnut size. There was no tendency toward confluence, attachment to skin or breakdown.

TABLE 1.—*Distribution of Lymphadenopathy in 35 Cases*

	Supraclavicular	Axillary	Pectoral	Epitrochlear	Inguinal	Femoral	Popliteal
Number of cases.....	1	35	3	11	35	35	3
Per cent.....	3	100	9	31	100	100	9

Bilateral axillary, inguinal and femoral adenopathy was present in all cases. In addition, epitrochlear adenopathy was found in 11 cases, pectoral adenopathy in 3 cases and popliteal adenopathy in 3 cases. Only 1 case presented a supraclavicular adenopathy (table 1).

The pectoral adenopathy was pronounced in all 3 cases seen, a string of lymph glands extending from the axilla along the margin of the pectoral muscle downward toward the nipple. In 1 case the pectoral and subpectoral adenopathy was pronounced and tender enough to be erroneously diagnosed as acute mastitis by the referring medical officer.

As a rule, however, acute inflammatory changes such as redness, edema and heat were absent. Episodes of retrograde (centrifugal) lymphangitis were not observed in this series. It must be emphasized that there was no noticeable correlation between periodically recurring pains and the objective appearance of glands.

The genital system was involved in all 35 cases, although degree and intensity of involvement varied greatly not only from case to case but also frequently within the individual during the period of observation.

The most frequently encountered genital involvement was a left funiculitis found in 21 cases. In 6 of these cases there was in addition a left varicocele. A right funiculitis was found in 5 cases, and in 1 additional case it was associated with a bilateral varicocele. The total number of cases presenting a varicocele was 10, a hydrocele 3 and an epididymitis 1 (table 2).

3. Manson-Bahr, P. H.: Manson's Tropical Diseases, ed. 11, Baltimore, Williams & Wilkins Company, 1943. Strong.[3]
4. Craig, C. F., and Faust, E. C.: Clinical Parasitology, ed 3, Philadelphia, Lea & Febiger, 1943.

The diagnosis of funiculitis was based on enlargement, often of a peculiar nodular character; thickening, edema and tenderness of funicular structures. It was found best to conduct this examination with the patient in the standing position. The two funiculi were examined simultaneously by rolling them between the thumb and the index finger of both hands, thus gaining impression as to their respective enlargement, nodulation, tenderness and edema.

As a further diagnostic aid it was found useful to introduce the finger into the external inguinal ring as is done in the routine examination of hernia. This procedure always elicited pronounced tenderness or frank pain presumably due to pressure of the sensitive edematous funiculus and spermatic cord against the pubic bone.

A less reliable but frequently helpful diagnostic aid was the absence of the cremasteric reflex on the affected side. It would seem reasonable to assume that edema and infiltration of the cremasteric muscle may interfere with the muscular reflex response on stimulation.

TABLE 2.—*Distribution of Genital Lesions in 35 Cases*

	Number of Cases				Per Cent
	Right	Left	Bilateral	Total	
Funiculitis	6	21	0	27	77
Varicocele	0	9	1	10	29
Hydrocele	2	0	1	3	9
Epididymitis	1	0	0	1	3

TABLE 3.—*Laboratory Data in 35 Cases*

	Leukocytosis Over 10,000	Sedimentation Rate		Eosinophilia	
		15 to 20 Mm.	Above 20 Mm.	5% to 10%	Above 10%
Number of cases	2	6	1	9	5
Per cent	6	17	3	26	14

Little difficulty was encountered in the diagnosis of hydrocele, varicocele and epididymitis, as these conditions corresponded exactly to the well known picture due to various other causes.

LABORATORY DATA

The following laboratory tests were performed in all 35 cases: repeated thick blood smears for microfilaria and malaria plasmodia, Kahn tests, sedimentation rates, blood counts and urine examinations. In addition, biopsy of inguinal lymph glands was done in 4 cases and hydrocele fluid examinations in 2 cases.

As stated before, blood smears taken at various intervals, day and night, were consistently negative for both filarial and malarial parasites. Careful examination of aspirated hydrocele fluid revealed no microfilariae in 2 cases.

Excised lymph glands were examined histologically by Lieut. A. P. Gewanter, M.C.R., U.S.N., and Capt. A. J. Segal, M. C., A. U. S. The diagnosis made was chronic hyperplastic lymphadenitis and follicular hyperplasia respectively. No evidence of filariae was found in sections. Excised lymph glands, furthermore, were incubated in saline solution for twenty-four hours and the tissue juice examined for filariae. The results were negative.

Urine examinations as well as Kahn tests were negative throughout. Red blood cell counts and hemoglobin determinations revealed no evidence of anemia. The leukocyte count was between 5,000 and 10,000 in all but 2 cases, in which the counts were 14,050 and 13,750 respectively. The sedimentation rate was normal in 28 cases, elevated to between 15 and 20 mm. per hour in 6 cases and above 20 (29 per hour) in 1 case.

The eosinophil count was found elevated to between 5 and 10 per cent in 9 cases and elevated to above 10 per cent in 5 cases, the highest being 19 per cent in 1 case (table 3).

Because of the fact that eosinophilia in the tropics is most frequently due to worm infections, stools of patients showing eosinophilia were repeatedly examined for evidence of helminthiasis. Stool specimens were examined fresh by the concentration and zinc sulfate flotation method. The results were negative.

COMMENT

The value of the old dictum that a diagnosis of infectious disease should not be made without demonstration of the causative organism is undisputed. Yet if one was to adhere to this dictum the early diagnosis of filariasis could not be made in most cases, for microfilariae were not found in this series as well as in large numbers of similar cases.[1] If the diagnosis should be delayed until such time as microfilariae become demonstrable it might prevent the only effective measure, namely early removal of the patient from the endemic area. It would furthermore create a large reservoir of carriers on whom the mosquitoes could feed and thus cause widespread propagation of the disease.

It is for this reason that a syndrome such as outlined must be depended on in order to reach at least a tentative diagnosis.

There seems little doubt that the clinical picture described was actually due to filarial infection. It is true that the findings were not as evident as described in the textbook picture nor were there typical filarial attacks accompanied by constitutional symptoms such as fever, general malaise and prostration. On the other hand there was a history of exposure to day and night biting mosquitoes in an area where the native population was known to be heavily infected with filariasis. There was a more or less generalized lymphadenopathy and there were present various types of genital lesions. Periodic aggravations of pains and swellings, so characteristic of the later stages of the disease, were commonly observed. However, the asymptomatic stage, also peculiar to late cases, was not noted in this series. Nocturnal pains and particularly nocturnal orchiodynia were frequent complaints.

Laboratory tests as performed were of little diagnostic help with the possible exception of an eosinophilia which was present in 40 per cent of these cases. Present efforts to devise a reliable laboratory test for the diagnosis of early filariasis would constitute a real advancement if successful. Meanwhile, however, the diagnosis must be based on clinical evidence and it is hoped that the symptom complex as outlined herein may serve toward this goal.

SUMMARY AND CONCLUSIONS

1. A clinical syndrome believed to be sufficiently characteristic to permit the presumptive diagnosis of filariasis in its early stages has been observed.

2. Laboratory data were of no value in the early diagnosis, with the possible exception of an eosinophilia which was present in 40 per cent of this series of 35 cases. Microfilariae were not found.

THE RELATIONSHIP OF POSTSCARLATINAL ARTHRITIS AND CARDITIS TO RHEUMATIC FEVER

LIEUTENANT COMMANDER ROBERT F. WATSON (MC), U.S.N.R.
SIDNEY ROTHBARD, M.D.
AND
HOMER F. SWIFT, M.D.
NEW YORK

Our purpose in this communication is to present the evidence of cardiac involvement occurring among 110 patients with scarlet fever and to correlate this involvement with rheumatic fever.

Cardiac injury, often associated with arthritis, has long been known to follow scarlet fever, but there still exists some question of its relationship to rheumatic fever. The cardiac and joint sequelae are still commonly designated as postscarlatinal carditis and arthritis without reference to this possible relationship. Many workers, on the other hand, have stressed the apparent close connection between postscarlatinal and rheumatic heart disease.[1]

It is well known that electrocardiographic abnormalities comparable to those seen in active rheumatic fever also occur during both the acute and the convalescent stage of scarlet fever. The reported incidence of such abnormalities has varied much, reaching as high as 86 per cent in the cases examined by Wickström.[2] This variation is in part due to differences in criteria for abnormal electrocardiograms employed by the different workers and in part to probable variation in host reactions.

The interpretation of the electrocardiographic changes has also varied among the different workers. Shookhoff and Taran[3] found only minor changes in the position of the RT or ST interval in 14 per cent and abnormalities in the shape and direction of the T waves in leads 1 and 2 in 10 per cent of 50 children with scarlet fever. They concluded that their findings in scarlet fever differed from those described in rheumatic fever in the comparative infrequency of abnormalities in the ventricular portion of the electrocardiogram, in the complete clearing up of all the abnormalities early in convalescence and in the absence of conduction disturbances. Wickström,[2] on the other hand, emphasized the striking similarity between the changes he observed in the electrocardiograms of patients with scarlet fever and in those with rheumatic fever but failed to comment on the possible etiologic relationship between the two diseases. Faulkner, Place and Ohler[4] observed prolongation of the PR interval beyond 0.20 second and T wave changes in lead 1 or 2 or both in 6 per cent of 171 patients. They also noted the striking similarity of the postscarlatinal electrocardiographic changes to those seen in active rheumatic fever and were doubtful whether the differences between the two conditions are fundamental. Roelsen[5] found electrocardiographic changes in 36 per cent of scarlatinal patients with arthralgia and in 26 per cent of those without arthralgia. In commenting on the possible etiologic relationship between the cardiac complications following scarlet fever and those of rheumatic fever he apparently believes that the scarlet fever patients who develop heart disease probably have both diseases, with a probable overlapping of the two conditions.

METHODS OF STUDY

In the present investigation only cases of unquestionable scarlet fever were included. All patients had typical scarlatinal rashes with postscarlatinal desquamation. Each patient was watched closely for any signs or symptoms of complications or sequelae. Routine symptomatic treatment was employed, and codeine rather than salicylates or aminopyrine was given to relieve discomfort. Sulfonamides were generally used only to combat developing purulent complications; many of the patients, however, received full therapeutic doses of sulfadiazine, together with a nose and throat spray containing 2.5 per cent sodium sulfadiazine, during postscarlatinal convalescence in an effort to clear up their streptococcic carrier states. Routine x-rays of the heart, lungs and paranasal sinuses were taken shortly after admission and when indicated thereafter.

Nose and throat cultures were made in duplicate on fresh 5 per cent sheep and rabbit blood agar plates on all patients on admission and routinely at weekly intervals during the remainder of their hospital stay or until two successive cultures were negative. The hemolytic streptococci were grouped and typed by the precipitin technic.[6] To avoid cross infections, only patients found to have the same type of group A streptococci were put together in rooms; otherwise they were strictly isolated.

Blood to determine the erythrocyte sedimentation rates and antistreptolysin and antifibrinolysin titers was obtained on admission and at weekly intervals. The erythrocyte sedimentation technic was that of Westergren;[7] the antifibrinolysin tests followed the method of Tillett, Edwards and Garner[8] as modified by Boisvert,[9] and the antistreptolysin determinations were made according to the method of Todd,[10] modified as previously described.[11]

With the subjects in the supine position, standard three lead electrocardiograms were obtained on all patients at the time of admission and at least once a week thereafter. Daily records were taken on 15 of the patients.

OBSERVATIONS

In this study there were 101 males and 9 females ranging in age from 17 to 45 years, with an average of 23 years. The majority had mild attacks of scarlet fever and only a few were severely ill. None were considered critically ill during their scarlatinal infection.

TABLE 1.—*Distribution of Groups and Types of Streptococci Recovered from 110 Cases of Scarlet Fever*

Number of Cases	Group	Type	Number of Cases	Group	Type
8	A	3	3	A	19 6*
1	A	3 14*	2	A	26
6	A	6	8	A	30
1	A	6-14*	1	A	33
6	A	17	2	A	38
1	A	18	5	A	No type †
65	A	19	1	C	—

* Two types recovered from these cases. The type listed first was considered probably responsible for the scarlatinal infection.
† These strains did not type by the precipitin technic. Three proved to contain the T antigen of type 14 by the agglutination method.

Hemolytic streptococci, generally as the predominating micro-organism, were isolated in large numbers on culture from the nasopharynx in every case, and all belonged to group A except one, which belonged to group C. The distribution of the various types is shown in table 1. The group A strains recovered from 5 of the patients could not be typed by the anti-M precipitin technic; 3 of these strains, however, proved to have the T antigen of type 14 by the agglutination method. Two different types were isolated from 5 patients; in these instances, as shown in table 1, the type strain considered to have caused the patient's scarlatinal infection is listed first, and it is believed that the patient was probably carrying the second strain at the onset of his illness.

Sixty-three patients suffered neither purulent complications nor nonpurulent sequelae. During the acute phase of their scarlatinal infection 3 members of this group had mild, transitory joint pains (arthralgia) which subsided with the disappearance of fever; and at no time were there any objective signs of arthritis or other associated rheumatic manifestations in these 3 patients.

Twenty-nine patients suffered purulent complications: 12 had sinusitis, 7 peritonsillar abscess, 5 otitis media, 2 pneumonia, 2 cervical lymphadenitis and 1 both sinusitis and otitis media. Four of these also had electrocardiographic abnormalities and are therefore included in the next group. In addition, 3 others of the 29 had arthralgia during the acute febrile stage of their disease similar to that described in the 3 patients in the first group.

Twenty-two patients showed definite electrocardiographic abnormalities either during the acute stage or late in convalescence from their scarlatinal infection; and it is this group of patients who are of particular interest. The electrocardiographic changes together with other signs and symptoms of possible rheumatic activity which occurred concurrently are shown in table 2.

* Indicates that these signs or symptoms may be attributed to the scarlatinal infection; → indicates trend of erythrocyte sedimentation rate or white blood cell count, the first figure is the lowest level attained prior to the onset of the sequela and the second figure is the highest level attained after the onset; those without arrows showed no significant change after the subsidence of the scarlatinal infection and during the sequela.
‡ This patient developed subcutaneous nodules.

The first signs or symptoms of cardiac involvement appeared relatively early in patients 1, 2 and 3; that is, within the first five days of their primary streptococcic infections. Two of these patients developed inverted T waves in all three limb leads, and the other developed transient, partial heart block. In addition to showing electrocardiographic abnormalities, all 3 patients complained of mild joint pains; 2 had precordial distress, and 1 of these had also a gallop rhythm. The fever, leukocytosis and elevated erythrocyte sedimentation rates in these patients may all be attributed to their scarlatinal infections. The clinical course of patient 2 is shown in chart 1.

Nineteen patients (4 through 22) developed their signs or symptoms of cardiac involvement during what may be designated as phase 3 of their illness; that

is, between the 10th and 56th days after the onset of their scarlet fever. In this group the temperature had returned to a normal level (phase 2) following the scarlatinal infection in all except patient 11; and in most instances the erythrocyte sedimentation rate and white blood count had returned to normal levels before the onset of the sequelae; that is, of phase 3. In most of these cases, therefore, it is possible to attribute the secondary rise in the temperature, leukocyte count and erythrocyte sedimentation rate to a complicating factor.

Seven of these 19 patients (4 through 10) had no definite clinical signs or symptoms of rheumatic activity contemporaneous with their electrocardiographic abnormalities. Four of these showed inversion of the T wave in lead 2 or in leads 1 and 2; the remaining 3 developed partial heart block. Patient 10 had a slight transient, secondary rise in temperature, leukocyte count and erythrocyte sedimentation rate associated with the electrocardiographic change, patient 9 had a brief secondary rise in temperature and patient 7 had only a transient leukocytosis. The associated increase in temperature, leukocyte count and erythrocyte sedimentation rate in patient 8 cannot be evaluated because of the appearance concurrently of coryza and cough. All of these patients appeared quite well at the time of the electrocardiographic abnormalities and, although repeatedly questioned, were without complaints. The clinical course of patient 10 is shown in chart 2.

Four patients (11 through 14) in addition to showing electrocardiographic abnormalities between the 10th and 35th days after the onset of their scarlatinal infection also complained of transient stiffness or mild pains in their joints, and 3 had accompanying malaise and anorexia. Three of them developed partial heart block and the remaining one showed an inverted T wave in lead 2. Three showed secondary increases in their erythrocyte sedimentation rates coincident with the electrocardiographic changes; 2 of whom also had transitory secondary rises in temperature and leukocyte count. The associated signs and symptoms of possible rheumatic activity in all 4 of these patients were mild and transient, and without the abnormal electrocardiograms they would have been difficult to interpret if not entirely neglected. The clinical course of patient 14 is illustrated in chart 3.

The remaining 8 patients (15 through 22) all had other signs and symptoms obvious enough to indicate the probable character of the sequela without the aid of the electrocardiogram. The associated signs and symptoms of rheumatic fever in patients 15 and 16 were, however, rather mild and transient. In the remaining patients (17 through 22) there could be little question regarding the diagnosis of rheumatic fever. All of them after making an apparently uneventful recovery from their scarlatinal infections developed secondary rises in temperature, leukocyte count and erythrocyte sedimentation rate with polyarthritis and definite electrocardiographic abnormalities varying from transient, partial heart block to heart block with dropped beats together with inversion of the T waves in all three leads. Patient 19 had signs of mitral stenosis when admitted with his scarlatinal infection; hence his attack undoubtedly represents a rheumatic recurrence. Patients 21 and 22 developed definite valvular disease while under observation and while receiving full doses of salicylates or aminopyrine respectively; 2 others, patients 15 and 17, developed soft apical systolic murmurs which were not transmitted; and in 1 of them the murmur disappeared with the subsidence in rheumatic activity. Patient 21 had typical subcutaneous rheumatic nodules. The clinical course of patient 17 is illustrated in chart 4.

Only 2 of the 22 patients showing definite electrocardiographic abnormalities had signs of or gave a history of having previously suffered from rheumatic fever or chorea. As already noted, patient 19 had definite signs of mitral stenosis on admission, although he denied having had rheumatic fever or chorea. Patient 3 gave a definite history of having had rheumatic fever in childhood, although on admission there were no abnormal cardiac findings.

SERUM ANTISTREPTOLYSIN O AND ANTI-FIBRINOLYSIN STUDIES

A summary of the serum antistreptolysin O and antifibrinolysin determinations made in the 110 cases of scarlet fever is presented in table 3. A rise in the serum antistreptolysin O content was considered significant only if the titer increased by two or more dilutions. An increase of one dilution over that shown on admission was regarded as a doubtful increase in titer. Patients were considered to have had a definite increase in the antifibrinolysin titration only if between admission and discharge there was a difference of at least 2 degrees of resistance to lysin of their plasma clots. Increases of 1 degree in resistance were considered as doubtful rises.

The results of the antistreptolysin O and antifibrinolysin tests have been divided into three groups according to whether the patients had uncomplicated scarlet fever, whether they suffered purulent complications or had electrocardiographic changes (table 3). The number of cases is too small to draw any conclusions by comparing the results obtained in one group with those in another. The total number of patients, however, is probably large enough to allow a comparison of the results of the two tests in the entire group. Ninety-four (85.5 per cent) of the patients showed a definite increase in their serum antistreptolysin O titers, while only 68 (61.8 per cent) showed a definite increase in the resistance of their plasma clots in the antifibrinolysin test. Thirteen (11.8 per cent) and 14 (12.7 per cent) had doubtful increases in their antistreptolysin O and antifibrinolysin titrations respectively, while only 3 (2.7 per cent) had no increase in antistreptolysin O titer against 21 (19.1 per cent) for the antifibrinolysin titer. Seven (6.4 per cent) of the patients had 4 plus resistance to lysis of their plasma clots on admission, so that further degrees of resistance could not be measured. These results are essentially the same as those previously reported by Mote and Jones [12] in 124 cases of scarlet fever.

COMMENT

An analysis of the complications and sequelae which occurred among 110 young adults with scarlet fever, who were intensively studied, has been presented. Group A streptococci were recovered on culture from the nasopharynges of 109 patients and a group C strain from the remaining one. Sixty-three patients had uncomplicated infections, 29 suffered purulent complications and 22, including 4 who also suffered purulent complications, developed definite and unequivocal electrocardiographic abnormalities, 3 during their acute infection and 19 later in postscarlatinal convalescence. It is this last group of patients with which this study is particularly concerned.

Electrocardiographic changes have been described in many acute infections,[13] including scarlet fever. The changes previously described in acute infections other than scarlet fever and diphtheria were generally observed during the acute phase of the disease, although slight increases in the auriculoventricular conduction time without other associated signs and symptoms have been noted during convalescence from pneumonia. In contrast to this, the changes noted in scarlet fever often occur late in convalescence and are frequently associated with transient joint pains, rises in temperature and leukocyte count.

It is now generally recognized that rheumatic fever is usually, if not invariably, preceded by a group A streptococcic infection (phase 1). It is also well known that there is ordinarily an asymptomatic period (phase 2) varying in length from a few days to several weeks between the acute streptococcic infection and the onset of rheumatic manifestations (phase 3). Today scarlet fever is considered a streptococcic infection. Whether the person with a streptococcic upper respiratory infection develops scarlet fever or only tonsillitis or pharyngitis seems to be determined largely by two factors; namely, the host's relative susceptibility to the erythrogenic toxin and the ability of the infecting streptococcus to produce this toxin in effective amounts. With these facts well established, it appears unreasonable to designate the symptom complex arthritis and carditis which follows scarlet fever by a different name from that applied to a similar complex which may follow tonsillitis or pharyngitis.

In view of these facts it is pertinent to consider the relationship to rheumatic fever of the condition causing the electrocardiographic abnormalities in the 22 patients considered in this study. Since the diagnosis of rheumatic fever rests on certain clinical signs and symptoms together with nonspecific laboratory evidence of infection and specific evidence of a previous hemolytic

streptococcic infection, we realize that the answer is not subject to experimental proof It is generally conceded, however, that carditis is one of the major manifestations of rheumatic fever, and also that one of the most characteristic signs of active rheumatic carditis is the occurrence of electrocardiographic abnormalities. Therefore, on the basis of these two factors, all of the 22 patients have suffered an infection with an agent recognized as playing an important role in inducing rheumatic fever and also had at least one of the characteristic signs of carditis

Without doubt 8 of these patients (15 through 22) had definite clinical evidence of rheumatic fever of varying severity. All 8 developed polyarthritis and electrocardiographic abnormalities accompanied by secondary rises in temperature, leukocyte count and erythrocyte sedimentation rate between the 19th and the 40th day after the onset of their streptococcic infection. Two, in addition, developed definite evidence of valvular disease, 1 of whom also had subcutaneous rheumatic nodules; and a third had mitral stenosis on admission as evidence of a previous rheumatic infection. Four other patients (11 through 14) differed from these 8 largely in that their rheumatic-like manifestations were milder and more transitory. All 4 had transient stiffness of the joints or mild joint pains concurrent with their electrocardiographic changes ten to thirty-five days after the onset of their scarlatinal infection; 2 in addition had slight secondary rises in temperature, leukocyte count and erythrocyte sedimentation rate; and a third had a slight increase in the erythrocyte sedimentation rate with precordial pain and gallop rhythm. Seven other patients (4 through 10) developed similar electrocardiographic abnormalities without other associated symptoms of rheumatic activity ten to fifty-six days after the onset of their scarlatinal infections. Patient 10 had a secondary rise in temperature, leukocyte count and erythrocyte sedimentation rate, while patient 9 had a brief secondary rise in temperature and patient 7 had only slight, transient leukocytosis associated with the electrocardiographic abnormalities.

From the foregoing description it is apparent that the difference between these three groups of patients is largely one of degree: it is quantitative rather than qualitative. All had a group A streptococcic infection—many with the same serologic type from the same scarlet fever epidemic—followed ten to fifty-six days later by definite electrocardiographic abnormalities of the type commonly observed in patients with active rheumatic carditis. It therefore appears most likely that the mechanism [14] by which the abnormal electrocardiograms were produced was the same in all of these patients irrespective of the occurrence of other rheumatic manifestations, and that all suffered from the same fundamental tissue injury following their streptococcic infection; namely, that characteristic of rheumatic fever.

It is somewhat more difficult to relate the changes found in the first 3 patients to those induced by rheumatic fever, largely because of the time element involved; for electrocardiographic abnormalities occur not infrequently during the acute phases of many different infections entirely unrelated to rheumatic fever. It is therefore quite possible that the early electrocardiographic abnormalities in these 3 were due to the same mechanism which cause similar abnormalities to occur in other acute infectious diseases. It is noteworthy, however, that all 3 of these patients had mild associated joint pains, 2 complained of precordial distress, and 1 of these had also a gallop rhythm. It may also be significant that 1 of the patients had previously suffered from rheumatic fever.

Mallory and Keefer [15] have recently described the histopathologic lesions in the hearts and other organs in 90 fatal cases of hemolytic streptococcic infections, including 47 cases of scarlet fever. The lesions found in the hearts of the scarlet fever patients consisted for the most part of focal accumulations of lymphocytes, plasma cells and histiocytes, at times with a few polymorphonuclear leukocytes, and a rare eosinophil. These lesions were most numerous in the subendothelial and perivascular connective tissues, which in general were the sites of the Aschoff bodies found in the control

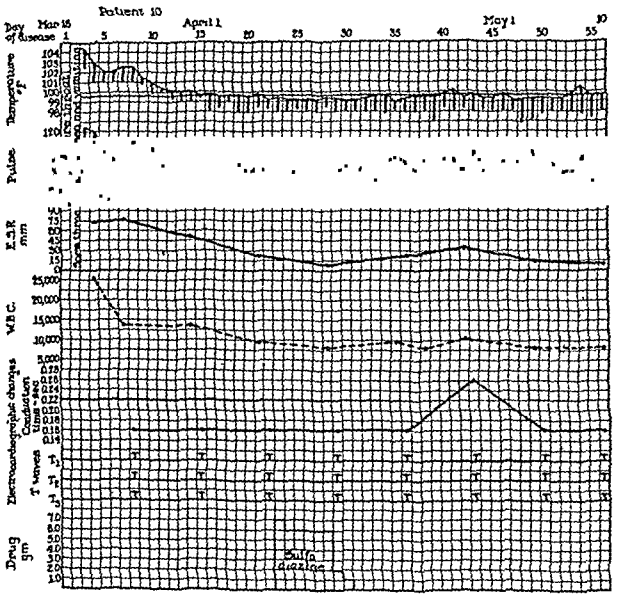

Chart 2.—Clinical course in case 10.

rheumatic hearts. Tying in with our clinical observations, it is of interest to note that these authors found these focal lesions to occur most commonly in the hearts of patients under 30 years of age who had survived their streptococcic infections for at least six to ten days. Mallory and Keefer propose the interesting hypothesis that these focal lesions may be an early stage of Aschoff body formation and present some evidence to support this concept. Similar lesions have been described by previous workers; [16] however, the interpretations of their findings have not been the same.

The cardiac abnormalities in the cases described in this study might well be explained on such a pathologic basis and may be interpreted as giving some clinical support to Mallory and Keefer's hypothesis. That is, those patients showing only transient changes late in convalescence may have had only focal collections of cells in their hearts, and these lesions then rapidly

14. We are aware that there is some evidence (Bruenn, H. G.: The ... ventricular Conduction in Acute Rheu... 1: 413 425 [April] 1937 and Keith, J. D.: ... rve in Rheumatic Fever, Quart. J. Med. ... *that the prolongation of the PR interval* associated with active rheumatic fever may be supraventricular in origin However, the great majority of cases described in this study presented other signs of infection, or symptoms of carditis or rheumatic fever, concurrent with the prolonged PR interval We therefore believe that in these cases the prolonged PR interval was indicative of carditis, regardless of the mechanism by which it is produced

regressed. Those patients who in addition to the electrocardiographic changes had transient joint pains with secondary rises in temperature, leukocyte count and erythrocyte sedimentation rate may have had more numerous and more widespread lesions, possibly persisting longer and progressing to a stage more comparable with that shown by rheumatic granulomas as described by Fahr,[17] Siegmund [18] and Eckert-Möbius.[19]

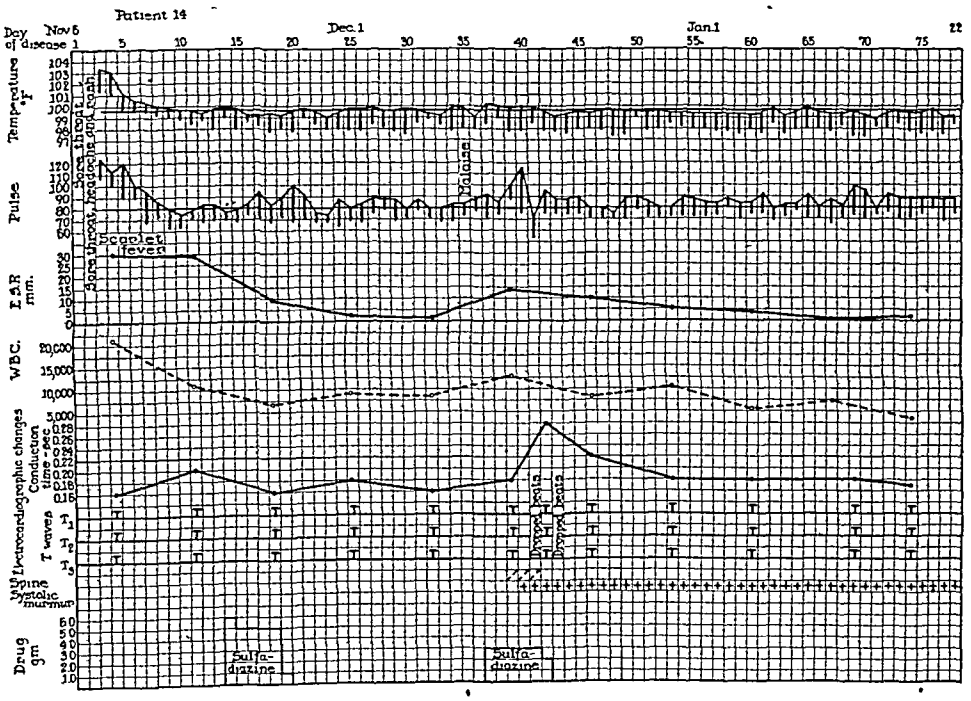

Chart 3.—Clinical course in case 14.

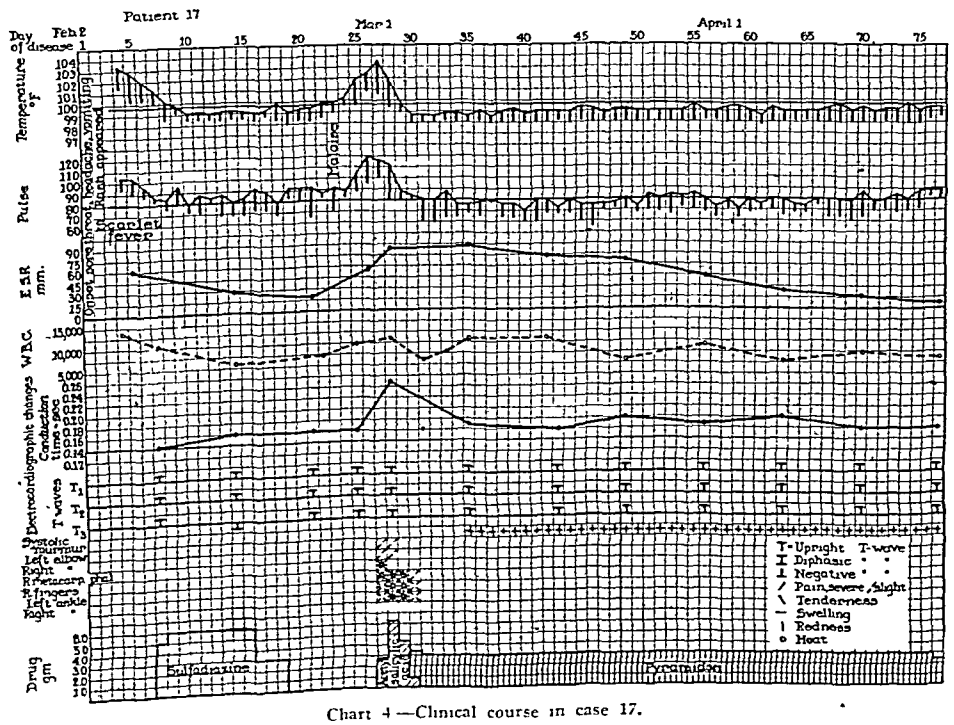

Chart 4.—Clinical course in case 17.

Those patients who had definite clinical attacks of rheumatic fever probably had comparable early lesions which, because of continued activity due to some unknown reason, in many instances progressed to form typical Aschoff bodies. Such an explanation would fit in well with our opinion that the fundamental tissue injury in all of these patients is essentially the same but that the response varies in intensity.

Whether the focal lesions described by Mallory and Keefer result from antigen-antibody reaction (allergic) in the tissues as these authors have suggested is impossible to say. Schick [20] and later Escherich and Schick [21] advanced the theory that the sequelae occurring from the end of the second week and lasting as long as seven weeks after the onset of the scarlet fever, with the greatest frequency in the third and fourth weeks, are allergic in nature. One of us [22] has previously emphasized this point of view. There is much evidence now to support such a hypothesis; namely, (1) the location and microscopic appearance of the lesions are consistent with an allergic reaction, (2) the lesions are more frequent late in the course of the disease than early and (3) similar types of lesions have been induced in rabbits by injection of foreign serums by Klinge,[23] Vaubel,[24] Junghans [25] and, more recently, Rich and Gregory.[26]

Nonpurulent arthritis or arthralgia is a well known concomitant or sequel of scarlet fever. Weaver [27] observed this complication in about 10 per cent of 5,595 cases and showed that the incidence increased with age. It was observed in 3.6 per cent of 10,000 cases at the Edinburgh City Hospital [28] and in 3.58 per cent of 153,607 cases in the Metropolitan Asylum Board Hospitals.[29] The arthritis or arthralgia may occur at any time during the course of the disease or in late convalescence. Secondary fever and leukocytosis often accompany the arthritis occurring in postscarlatinal

convalescence. Most observers agree that the arthritis which occurs in postscarlatinal convalescence cannot be distinguished from the arthritis associated with rheumatic fever. Actually, we believe that there is no reason to differentiate the two, because they are probably due to the same fundamental tissue injury. If frequent electrocardiograms were taken in these so-called postscarlatinal arthritis cases, a high percentage would probably show abnormal changes, as was previously observed by Roelsen.[29]

All of the patients considered in this report who developed arthritis or arthralgia late in postscarlatinal convalescence also showed abnormal electrocardiograms. Six patients in our series, however, had mild transient joint pains without electrocardiographic or other rheumatic manifestations during the early acute phase of their streptococcic infection. Whether the joint manifestations in these early cases is due to the same mechanism that produces those late in convalescence is difficult to answer at present. It is noteworthy, however, that the arthralgia seen during the acute stage of scarlet fever is rarely accompanied by evidence of exudation, such as is frequently seen with the arthritis later in convalescence. Healey[30] and Rhoads and Afremow[31] have found that a high percentage of patients developing joint pains following the injection of streptococcic erythrogenic toxin give a past history or have evidence suggestive of previous rheumatic infection. They therefore interpret their results as evidence that these individuals are sensitive to the erythrogenic toxin or other streptococcic products in the sterile filtrate injected. The mechanism of the arthralgia seen early in scarlet fever might be explained on a similar basis, but, on the other hand, it might be due to a direct toxic damage to the tissues.

Many patients with rheumatic valvular disease fail to give a history of previous attacks of rheumatic fever or chorea. White[32] estimates that a definite history of rheumatic fever can be elicited in only about 70 per cent and a history of chorea in another 5 to 10 per cent. Recently Levy, Stroud and White[33] found that 68.8 per cent of 2,250 rejected draftees with definite rheumatic valvular cardiac disease failed to recall any symptoms or signs of rheumatic fever or chorea earlier in life. Whether patients such as we have observed, with only electrocardiographic abnormalities or with associated mild arthralgia, contribute to such a "history negative" group cannot be answered at present. One might argue that they do not, because the brevity of the signs and symptoms of rheumatic carditis would hardly be expected to lead to severe and permanent valvular damage. Since we consider that these patients suffered true first attacks of rheumatic fever, we therefore believe that they should be regarded as more liable to rheumatic recurrences than normal subjects and as more likely to develop permanent cardiac damage following subsequent hemolytic streptococcic infections. Because the extent of permanent cardiac damage in rheumatic subjects is roughly proportional to the number of attacks of rheumatic fever they have suffered, it seems only logical to place this class of patients in a category to which special measures should be applied for the prevention of hemolytic streptococcic infection.

* Four other patients also had purulent complications in addition to electrocardiographic abnormalities and are therefore included in the latter group

SUMMARY AND CONCLUSIONS

The purulent complications and nonpurulent sequelae which occurred among 110 cases of scarlet fever in young adults who were intensively studied were analyzed. Group A streptococci, representing at least thirteen different types, were recovered on culture of the nasopharynges of 109 patients and a group C strain from the remaining one. Antistreptolysin O and antifibrinolysin titrations were made with the serums and plasmas respectively of all patients at weekly intervals.

Sixty-three patients had uncomplicated infections and made uneventful recoveries; 29 suffered purulent complications; and 22, including 4 who also had purulent complications, developed pronounced and unequivocal electrocardiographic abnormalities comparable with those seen in patients with active rheumatic carditis. Three of these 22 patients developed abnormal electrocardiograms during their acute streptococcic infection and the other 19 during postscarlatinal convalescence. It is this latter group of 19 patients who are of particular interest in this study.

Eight of the 19 patients who developed electrocardiographic abnormalities during postscarlatinal convales-

cence had definite clinical attacks of rheumatic fever of varying severity. Four others differed from these 8 in that their rheumatic-like manifestations were milder and more transitory. The remaining 7 during a comparable period in their convalescence developed similar electrocardiographic abnormalities without other symptoms of rheumatic fever, although several had brief secondary rises in temperature, leukocyte count or erythrocyte sedimentation rate. The difference between these three groups of patients is quantitative rather than qualitative, and we believe that all suffered from the same fundamental tissue injury following their streptococcic infection; namely, that characteristic of rheumatic fever.

AN OUTBREAK OF SONNE DYSENTERY

LIEUTENANT COLONEL JOSEPH F. PAINTON
Assistant Professor of Medicine, University of Buffalo School of Medicine, on Leave of Absence
AND
MAJOR SAMUEL HANTMAN
MEDICAL CORPS, ARMY OF THE UNITED STATES

History indicates that bacillary dysentery is almost as old as war itself. It is said that dysentery decimated the army of Napoleon in its retreat from Moscow. Though no accurate figures are available from the Revolutionary War, there were 285,000 cases of dysentery in the federal army alone during the Civil War.

In World War I bacillary dysentery was the most important disease in the British armies in the Eastern Mediterranean area and at Gallipoli was responsible for almost 100,000 casualties. Many writers have claimed that dysentery was more important than the Turks in driving the British troops out of this area.

According to the Surgeon General's report of 1917-1918, 87,700 cases of dysentery and common diarrhea occurred among the American troops in World War I.[1] The average time lost from duty was eleven days in each case. The admission rate in 1917-1918 was 18.45 per thousand, while for the ten year period from 1930 to 1940 it dropped to 1.8 per thousand. Again in 1940-1942, with the mobilization of troops, the rate rose to 10.17 per thousand. It is apparent from these statistics that in times of war, when close congregation of large forces of soldiers is necessary, bacillary dysentery becomes one of the most important diseases encountered by the military surgeon.

World War II has been no exception. A recent report by the Preventive Medicine Division of the office of the Surgeon General,[1] which includes statistics only up to April 1942, already shows data collected on 328 outbreaks of diarrhea. Two hundred and fifty-five occurred in the continental United States and 73 abroad, affecting nearly 25,000 soldiers. Laboratory studies, made on approximately 100 of these outbreaks, indicated that roughly 50 per cent were due to one of the members of the bacillary dysentery group.

This presentation is concerned with an outbreak which occurred in a basic training center of the Army Air Forces during the summer of 1943, persisting in epidemic form for about eight weeks and then gradually tapering off.

Epidemiology revealed that the source of this outbreak began at a new target range located at some distance from the main camp but connected with it. Investigation clearly indicated that the epidemic was fly borne. Bacteriologic studies by Cohn[2] of the hospital laboratory and further corroborated by Kuhns[3] revealed the causative organism to be Bacterium sonnei. During this period of approximately four months following the onset of the outbreak, positive cultures of this organism were obtained in 181 cases.

The clinical picture of this group of cases was typical of the description found in most textbooks for the Sonne type of bacillary dysentery. By and large the cases were mild in severity. The duration of active symptoms was only three to four days. The onset in the majority of cases was sudden and the chief symptoms were chills, fever, malaise, backache and cramping abdominal pains associated with diarrhea and usually tenesmus. In most patients the diarrhea was only moderately severe, with the number of stools ranging from 2 to 20, for an average of 8 daily. The stools were watery and greenish mucoid in character in the vast majority of cases. In 10 cases (5 per cent) the stools were tinged with blood. There were no gross hemorrhages. Tenesmus was present in most of the cases but was not severe in any. Fever was present in 75 per cent of the cases admitted in the acute stage, ranging from 99 to 104 F., with an average of 101 F. Chills or chilly sensations were present in nearly 50 per cent of the cases. Although most of the patients showed some evidence of malaise or weakness, none were sufficiently prostrated from toxicity or dehydration to warrant the parenteral administration of fluids. The fever persisted as a rule for two to four days, and the diarrhea subsided after four to seven days with or without specific treatment. There were no complications and no fatalities.

On admission all patients were given bed rest, either a bland or a high protein low residue diet, and camphorated tincture of opium or morphine, depending on the severity of the diarrhea.

During the acute stage the leukocyte count varied from 6,400 to 10,000 per cubic millimeter of blood, averaging 8,200, with 62 per cent polymorphonuclear neutrophils and 37 per cent lymphocytes. It is obvious that most of these cases had perfectly normal total and differential leukocyte counts.

Sigmoidoscopy was performed in 50 cases (27 per cent) during the acute phase of the disease. The findings varied from mild to severe hyperemia and edema to granular mucosal changes and superficial ulceration. The latter occurred in only 5 cases (2.7 per cent).

The diagnosis was confirmed by culture of either fresh stool specimens, rectal swab utilizing the Hardy[4] rubber tube technic or by direct sigmoidoscopic swab. These specimens were inoculated on SS (shigella, salmonella) agar and the organism further identified by fermentative and specific serologic reactions. Emphasis should be placed on the fact that in most cases the culture reports were not available until the acute manifestations of the disease had subsided. It is clear then that any evaluation of treatment would be essentially a determination of the efficacy of various types of therapy in eradicating the carrier state.

As it appeared that a large number of soldiers were developing the disease, an excellent opportunity was at our disposal for the study and appraisal of existing methods of specific treatment.

The use of sulfonamides in the treatment of bacillary dysentery is not particularly new. Many reports have appeared during the past four years attesting the value of sulfonamides on the course of acute, chronic or the carrier state of bacillary dysentery. The pioneer work of Marshall and his associates [5] reported in January 1941 marked the advent of chemotherapy in bacillary dysentery when they demonstrated the value of the drug sulfaguanidine in rendering negative the stools of 15 out of 17 children affected with the disease. Since then other workers [6] have shown the value of this drug in controlling relatively large epidemics of the various forms of this disease both in the Middle East and in Puerto Rico.

In 1942 Poth, Knotts and their co-workers [7] reported on the efficacy of a newer sulfonamide, the succinyl salt of sulfathiazole, which, they reported, had a striking bacteriostatic effect not only against the usual intestinal flora but also against the strains of Shiga, Flexner and Sonne dysentery bacilli.

Hoagland, Harris and Raile,[8] in a series of 45 carriers of Bacterium paradysenteriae, divided into two groups, observed equally good results with either of the aforementioned drugs. They employed a dosage of 20 Gm. daily for six days and; regardless of the drug used, obtained 100 per cent cure of the carrier state. This work was supported by lengthy observations of cultures over a period of seventeen to sixty days.

Smyth and his associates,[9] using a similar dosage of sulfaguanidine and approximately the same dosage of succinylsulfathiazole, also observed fairly satisfactory results. However, in view of failures with each type of therapy and the potentially greater toxic effects of sulfaguanidine, they concluded that succinylsulfathiazole was the drug of choice.

Paulley,[10] in reviewing his experiences in the treatment of dysentery in the Middle East, found that sulfapyridine was more effective than sulfaguanidine in the management of acute bacillary dysentery. Unfortunately, stress of circumstances prevented complete follow-up cultures in this series.

Yannet, Leibovitz and Deutsch,[11] using plain sulfathiazole in the treatment of 27 patients suffering from Sonne dysentery, found that this sulfonamide, though producing a more rapid clinical recovery, allowed more cases to persist as carriers than those not treated in this manner.

Page,[12] in his recent report of 500 cases, 208 of which proved to be due to members of the genus Shigella, found after careful follow-up cultures 97.3 per cent cured with 130 Gm. of sulfaguanidine given in a ten day period. Page used as a secondary treatment sulfadiazine in a dosage of 22 Gm. given in a five day period and was able to render the remainder (2.7 per cent) dysentery free.

Eisenoff and Goldstein,[13] using all of the aforementioned sulfonamides except sulfapyridine in an outbreak of Sonne dysentery, found all of these agents effective in 90 per cent of the cases and eliminated the carrier state in the remaining 10 per cent by a second administration of the drug.

From this review it is evident that all of the sulfonamides have a beneficial action in acute bacillary dysentery but possess a somewhat varying effect on the eradication of the carrier state.

Since the outbreak of World War II, sulfaguanidine has attained considerable prominence in the treatment of this disease. However, it is apparent that a wide divergence of opinion exists as to the optimum dosage, with amounts varying from 4 Gm. daily for seven days [14] to as high as 20 Gm. daily for six days.[8]

Prior to 1942 little had appeared in the literature regarding the toxic effects of sulfaguanidine. Cole [15] reported a severe sulfaguanidine intoxication in a case of ulcerative colitis. He utilized a dosage of 0.1 Gm. per kilogram (roughly 6-7 Gm.) initially followed by 0.05 Gm. per kilogram (3.5 Gm.) at four hour intervals. After 110 Gm. had been given a severe intoxication developed, which was manifested by vomiting, fever, oliguria and a morbilliform rash. At the height of this reaction the blood level was only 2 mg. per hundred cubic centimeters. Recently Whyte [16] reported evidence of renal irritation in 14 out of 25 cases treated. He utilized only 9 Gm. a day for three days followed by 6 Gm. a day for four days (total dosage 51 Gm.).

Bunting and Levan,[17] reporting on the treatment of 191 soldiers with bacillary dysentery, noted objective evidence of toxicity in 11.5 per cent and subjective manifestations in 20 per cent. Crystalluria was found in 26.5 per cent, drug fever in 9.4 per cent, skin reactions in 5 cases and transient hematuria in 4. They gave 3.5 Gm. three times daily for a ten day period, a total dose of 105 Gm. They concluded that sulfaguanidine is not without its dangers and that caution in its administration should be exercised. Schnitker,[18] in reviewing the literature on the toxic manifestations of sulfaguanidine, stated that the overall toxicity was 1 to 2 per cent and concluded that the untoward effects seem slightly more frequent with this drug than with succinylsulfathiazole.

In view of the foregoing reports it was decided to assess the value of sulfaguanidine in the treatment of bacillary dysentery, with utilization of the smaller dosage as recommended by Opper and Hale.[14]

The other sulfonamide chosen was succinylsulfathiazole. This was selected in view of the reported infrequency of toxic effects.[19]

Criticism might be directed to the fact that the sulfonamides producing a high blood concentration were not considered. We are fully aware that acute bacillary dysentery is not a condition confined to the intestinal mucosa but a tissue and systemic disease. Thus during the acute diarrhea phase it is probable that sulfonamides producing immediate high blood levels are desirable. However, as previously mentioned, most of the patients in this study were over the acute stage in such a short time that the problem resolved itself chiefly into eradication of the carrier state. In this situation sulfonamides producing a low blood level and a high bowel concentration might be the drugs of choice.

TABLE 1.—*Results in 181 Cases*

	Types of Therapy	No. of Cases	Results: Cures: No. of Cases	Results: Cures: Per Cent	Results: Failures: No. of Cases	Results: Failures: Per Cent
1	Controls	33	26	79	7	21
2	Sulfaguanidine (1 Gm. q. i. d. 7 days)	21	16	76	5	24
3	Sulfaguanidine (2 Gm. q. i. d. 7 days)	7	6	85.9	1	14.19
4	Succinylsulfathiazole 0.25 Gm./Kg. body weight per day for 7 days	71	70	98.5	1	1.5
5	Polyvalent bacteriophage 2 capsules (50 mg. each) q. i. d. for 2 days	49	40	81.7	9	18.3
	Total number of cases	181	158	87.3	23	12.7

As failures have been reported with all the aforementioned chemotherapeutic agents, it was only appropriate to investigate the status of the bacteriophage as a means of overcoming the carrier state. The theory of its use in the treatment of bacillary dysentery is not new. As long ago as World War I d'Herelle[20] attempted the treatment of bacillary dysentery with this specific agent, with questionable results. More recently Gantenberg,[21] in an epidemic of bacillary dysentery following the German invasion of Poland, reported inconclusive and unsatisfactory results with a polyvalent bacteriophage made by Behring. On the other hand, Compton[22] has recommended it in Cairo, where it is said to have become quite popular.

PLAN TO STUDY

In the beginning the original intention was to divide all of the cases into four equal groups, but as the epidemic assumed greater proportions it became imperative that more cases be given the type of therapy which had shown the greatest degree of success. These four groups were treated in the following manner:

1. Controls, treated symptomatically.
2. Sulfaguanidine 1 Gm. four times daily for seven days, total dose 29 Gm.
3. Succinylsulfathiazole 0.25 Gm. per kilogram of body weight daily for seven days; average total dosage 130 Gm.
4. Polyvalent dysentery bacteriophage two capsules four times daily for two days, each capsule containing 50 mg.

The last named material was supplied through the courtesy of Larkum[23] of the Army Medical School. This bacteriophage was active against the entire Shigella genus and was lyophilized so that each 50 mg. was equivalent to 25 cc. of the original phage.

Although many other patients with diarrhea were admitted to the hospital during this outbreak, only those were treated who were proved by culture to have Bacterium sonnei infection. Table 1 reveals the results obtained in 181 proved cases with the different types of therapy. It will be noted that the table includes an additional group. The creation of this group was due to a relatively high percentage of failures when the smaller dosage schedule of sulfaguanidine was used. The dosage of sulfaguanidine was doubled in this new group, 2 Gm. being given four times daily for a seven day period.

TABLE 2.—*Treatment of Failures*

	Unsuccessful Primary Therapy	Number of Failures	Successful Secondary Therapy: Control Management Alone	Sulfaguanidine, 1 Gm. q. i. d.	Sulfaguanidine, 2 Gm. q. i. d.	Succinylsulfathiazole, 0.25 Gm./Kg. B. W./Day	Polyvalent Bacteriophage, 2 Capsules q. i. d.	Succinylsulfathiazole and Bacteriophage
1	Controls, symptomatic treatment	7	0	0	0	2	5	0
2	Sulfaguanidine, 1 Gm. q. i. d. 7 days	5	0	0	0	0	3	2
3	Sulfaguanidine, 2 Gm. q. i. d. 7 days	1	0	0	0	1	0	0
4	Succinylsulfathiazole, 0.25 Gm./Kg. daily 7 days	1	0	0	0	0	1	0
5	Polyvalent bacteriophage, 2 capsules q. i. d. 2 days	9	1	0	0	1	3	4
	Total	23	1	0	0	4	12	6

In order to make this tabulation completely understandable, the criteria of cure and the determination of failure must be stated. Cultures were taken three days after the cessation of treatment in all groups except the controls. In the latter the stools were cultured for the first time after the diagnostic culture, nine days after admission. Following this initial culture, successive cultures were taken on the fifth day, twelfth day and nineteenth day following cessation of therapy. If the first or any of the succeeding cultures remained positive for the organism, the case was considered a treatment failure and secondary treatment immediately instituted.

From table 1 it is clear that the greatest percentage of cures was obtained with succinylsulfathiazole, while with the smaller dosage schedule of sulfaguanidine and the prescribed dose of bacteriophage the percentage of cures was actually no better than in those cases in which only a symptomatic regimen was given. It should be noted, however, that when the dosage of sulfaguanidine was doubled the percentage of cures showed a small but definite increase.

It is also apparent from table 1 that some failures occurred with all types of therapy, so that secondary treatment was necessary.

20. d'Herelle, F.: Bacteriophage and Its Behavior, Baltimore, Williams and Wilkins Company, 1926.
21. Gantenberg, cited by Stitt, E. R., and Strong, R. P.: Diagnosis, Prevention and Treatment of Tropical Diseases, ed. 6, Philadelphia, Blakiston Company, vol. 1, pp. 554-556, 578.
22. Compton, Arthur: Treatment of Bacillary Dysentery, Brit. M. J. 2:280 (Aug. 23) 1941.
23. Larkum, N. W.: Personal communication to the authors.

Table 2 demonstrates the type of therapy that was successful after the primary treatment had failed.

There were no failures after a second course of therapy with the twenty-one day period of follow-up cultures. We are fully cognizant of the fact that some of these cases might have reverted to a positive carrier state some weeks or months later. However, in a basic training center where the men are assigned for only a limited period of time, further observation of cultures beyond the twenty-one day period was not feasible. From table 2 it seems likely that a combination of a sulfonamide with a potent bacteriophage may offer some promise of success in overcoming the obstinate carrier problem.

Blood levels were obtained at the beginning and end of the treatment in the majority of patients receiving either one of the sulfonamides. With sulfaguanidine in the low dosage group, the blood levels ranged from 0.9 to 2.0 mg. per hundred cubic centimeters, with an average of 1.2 mg. per hundred cubic centimeters. It is clear that even with very small doses this drug attained a comparatively high blood concentration. On the other hand, with succinylsulfathiazole, when used in doses roughly four times the amount of sulfaguanidine, the blood showed only concentrations varying from 0.12 to 0.31 mg. per hundred cubic centimeters for an average of 0.22 mg. per hundred cubic centimeters. However, despite the wide variance in the range of blood levels, when the two sulfonamides were used there were no toxic reactions in either group. The only untoward reaction noticed was in a few patients on succinylsulfathiazole therapy, who complained of slight frequency and burning on urination.

CONCLUSION

1. One hundred and eighty-one cases of dysentery due to Bacterium sonnei were studied.

2. Low dosage treatment (4 to 8 Gm. per day for seven days) with sulfaguanidine was ineffective in eliminating carriers. No comparison relative to the effectiveness of the two sulfonamides can be made, owing to the gross disparity in dosage used.

3. Succinylsulfathiazole 0.25 Gm. per kilogram daily for seven days was efficacious in the eradication of the carrier state.

4. Polyvalent dysentery bacteriophage was no more effective than symptomatic management in rendering the patient dysentery free.

Beginning of Modern Dentistry.—The professional life of the "father of modern dentistry," Pierre Fauchard, began in the reign of the Sun King of France, Louis XIV, at whose gilt edge, resplendent court good looks—which might be marred by bad teeth—often carried off the fairest favors. Fauchard himself, graceful, elegant, courteous, might have passed for an idle nobleman. Actually he worked hard, first at Angers and later (after 1719) in Paris, at pulling, filling and reconstructing teeth and studying dental disease. Almost single handed he established dentistry as a respectable profession; before him it had been left to itinerant tinkers, vagabonds and boorish charlatans who made "tooth drawing" a laughable public spectacle. Fauchard had been trained as a naval surgeon; hence he chose the title "The Surgeon-Dentist" ("Le Chirurgien-Dentiste") for his great two volume textbook, published at Paris in 1728. Among the "aphorisms of dentistry" here selected and arranged from this first dental textbook none bears repetition today more forcibly than that one relating to the cleansing of the teeth.—The Autobiography of Science, edited by Forest Ray Moulton and Justus J. Schifferes, New York, Doubleday, Doran & Co., Inc., 1945.

DYE POISONING IN THE NURSERY

A REVIEW OF SEVENTEEN CASES

JULIAN GRAUBARTH, M.D.
CHARLES JAMES BLOOM, M.D.
FRANCIS CARTER COLEMAN, M.D.
AND
HARRY N. SOLOMON, B.S.
NEW ORLEANS

Instances of acute poisoning by aniline and its derivatives occur not infrequently. Many of the cases reported among industrial workers and particularly in children could have been prevented had the possibility of this condition been kept in mind. It is also true that the recognition of this dye intoxication would not be so indefinite and always forthcoming if workers would be constantly on the alert in places where it is apt to occur. Therefore it is our purpose in this paper to reemphasize and warn all those concerned that this condition should never be underestimated and that today negligence of some sort is usually its chief source.

HISTORY

There have been many interesting reports on the toxic effects of aniline, its derivatives and coal tar, their mother substance. The first series of cases due to aniline-stamped diapers was in 1886. Rayner [1] reported 17 cases which appeared in London at this time. The cause of the cyanosis which appeared in these babies was an unsolved riddle among London doctors for many months. In 1929 Zeligs [2] reported 4 cases of aniline and nitrobenzine poisoning in infants. All recovered. It was found that 3 of these cases were due to skin absorption of dye from freshly stamped pads and 1 was caused by inhalation of vapors used in bedbug exterminating. He stated that articles were rendered harmless by boiling after dyeing or freshly stamping them.

Two years later Weinberg [3] described 13 cases, the poisoning resulting from the baby's body having been wrapped in clothing freshly marked with hospital identification lettering. In practically all of the cases the printing was found to be in contact with some part of the infant's body. Definite staining was found in 8 of 13 cases. The subsequent course of these children showed that all were fully recovered in from twenty-four to seventy-two hours without any observable harmful effects.

Neuland [4] reported 3 similar cases in which poisoning occurred in the same manner and Ewer [5] saw 5 infants with aniline intoxication. Two of the latter group had extensive furunculosis and therefore absorbed more of the dye. All of this last group recovered.

From the Department of Pediatrics, Touro Infirmary.

The members of the staff of Touro Infirmary gave permission to use their cases in the compilation of this report.

CHEMISTRY

Aniline has the chemical formula $C_6H_5NH_2$ and is aminobenzine. It is a colorless, oily liquid with no medicinal use. When aniline intoxication occurs in the body methemoglobinemia develops. This condition, of the blood is probably the chief cause of the presenting symptoms and is due to paraminophenol and hydroxyphenylhydroxylamine,[6] which are intermediate oxidation products of aniline in the body. When the methemoglobin forms there is a short reversible reaction, with some of it being changed back into hemoglobin. Methemoglobin is a true oxide of heme and native globulin. Oxygen cannot be removed from this combination except by chemicals: methemoglobin is not capable of acting as a respiratory pigment, and a functional anemia results because of the diminution of hemoglobin available for oxygen transport.

SYMPTOMS

When there is 5 Gm. of reduced hemoglobin, cyanosis in the skin and mucous membranes appears. Some authors[7] believe that the grayish blue cyanosis which occurs with aniline intoxication is a specific symptom. They maintain that it is due to the deposition of a specially formed pigment in the subcutaneous tissues. This is borne out for them by the fact that in spite of the cyanosis the respiration remains rhythmic. This is not true when cyanosis is caused by cardiac decompensation or pulmonary involvement. Nevertheless, cyanosis depends to a large extent on the amount of methemoglobin in the body. This condition, which turns the skin slate colored, is one of the most striking of all symptoms encountered with the intoxications.

Aside from the alarming and acute symptoms concerned primarily with the companionable linkage of the blood hemoglobin and respiratory physiology, other symptoms often draw one's attention. These are evident in the nervous symptoms such as convulsions, tremor, vertigo, tinnitus and later paralysis. Dulstin[7] explains these and other nervous symptoms by saying that aniline has a direct and toxic effect on the central nervous system. He maintains that the great abundance of lipoids in the nervous tissues probably aids in the solubility of unchanged aniline found in the blood stream. Of course, many of these symptoms and signs are not detectable in the newborn for obvious reasons.

Often one sees prominent cardiac disorders having to do with disturbances in the conducting mechanism of the heart. In a group of animal experiments, Young and his associates[8] found that aniline had a direct toxic effect on the heart muscle. Proper amounts of the dye produced heart blocks and all varieties of arrhythmias. Young maintains that in acute aniline poisoning death is usually cardiac. In this series, as will be shown later, death was not due to cardiac disorder.

REVIEW OF CASES

On Jan. 5, 1944 at the Touro Infirmary a near tragedy was seen in the nursery, which was occupied by 32 babies. Seventeen of the babies unexpectedly and gradually became cyanotic and began to breathe with extreme difficulty. The diagnosis of this extensive and bizarre finding was finally made by Dr. Julian Graubarth, who remembered such a condition to have occurred in Cincinnati in 1929. The cause of these sudden symptoms was finally traced to a particular set of diapers which were stamped with ink containing aniline dye. These were accidentally sent to the nursery without first having been laundered or sterilized. The infants then absorbed the aniline through the skin of their buttocks.

At this time it would probably be wise to point out a few of the trying situations that hospitals and particularly nurseries have found themselves confronted with during the present war. There has been a shortage of diapers both in hospitals and in civilian life; therefore it can easily be seen how a nursery can exhaust its ready supply and then hastily seek what diapers it has left if the necessity becomes acute. Too, hospitals have experienced a frequent turnover in employees. This has resulted in the constant necessity of training new workers as well as combating serious problems that arise owing to lack of experience and breaks in hospital technics. Innumerable obstacles, as those that have been mentioned, have arisen in hospitals as they have in industry. It is not unlikely that situations which present themselves in the future will act as precipitating or predisposing factors to similar outbreaks.

At the time of the mishap at Touro there were 32 babies in the nursery, although only 17 developed evident aniline intoxication. All of those affected wore the unwashed diapers stamped with the dye, while the remaining 15 were wearing old diapers. A review of case histories of those children developing aniline dye poisoning revealed the following findings: One of the first things to be noted was varying degrees of anorexia in some, while others showed no disinclination to feed. All the babies showed signs of cyanosis, but this was most evident in 9 cases and lasted, on an average, ten to fourteen hours. Respiration was accelerated in every instance, but it was difficult in only 5 babies. Irritability, vomiting and loose stools were each noted in 3 cases. Other findings were hematuria (2), distention (2), jaundice (1) and an enlarged spleen (1). It was noted among most of the infants that the cry was reduced in intensity, and only 1 case showed what was thought to be a mild convulsive seizure. After ten months there have been no reports of cerebral damage. There are no reports on a refractory anemia which often follows this type of intoxication.

One infant, L. W., had serial blood pictures which revealed the following: On January 9, four days after the onset of the poisoning, the blood determinations revealed a red blood cell count of 2,500,000 and a hemoglobin of 4.9 Gm. One month later the red blood cells had risen to 3,000,000 per cubic millimeter and the hemoglobin to 9.7 Gm. The last determination was on June 9, 1944, at which time the red blood cell count was 4,300,000 and the hemoglobin was 11.6 Gm. These figures show that at the end of six months there was a complete return to normal of the red blood cell count and the hemoglobin. This picture was typical of many of the other infants.

Unfortunately, the final analysis showed that of the 17 babies involved 4 failed to survive. It is interesting,

to note that of the 4 deaths 3 were of premature infants, 2 of these being twins. The premature twins died of bronchopneumonia approximately three weeks later. The pathologists reported that the cause of death in the third premature child was from an intracranial hemorrhage complicated by bronchopneumonia. The fourth fatality was due to a generalized peritonitis caused by the Friedländer bacillus. In this infant no other pathologic change could be found, except for a diffuse reddening on both thighs which appeared to be a diaper rash, although an extensive search was made.

For the sake of brevity, 1 typical case will be described in detail, since many of the cases were similar in signs and symptoms:

Baby M., born several days previously, of an uncomplicated delivery, weighed 7 pounds 4 ounces (3,290 Gm.). This infant became dusky during the morning of Jan. 5, 1944. Its condition gradually became worse and respiration more difficult; therefore oxygen and 5 per cent carbon dioxide was started early in the afternoon. At this time the temperature was 99.0 F. By 5 p. m. of the same day no improvement was noticed and it was decided to administer 2 mm. of mkethamide. There was no reaction to this drug and the color became progressively worse, now being a grayish blue. At 9 30 p. m. methylene blue ½ grain, 0.032 Gm. (5 cc.), was given intravenously as well as a transfusion of 60 cc. of whole blood. Oxygen was administered until 8 o'clock the following morning. During the first day the baby was fed at 2 and 10 p. m. 1½ ounces of the nursery's routine formula.

On January 6 methylene blue was again given in the same dosage at 12, 3, 6, 9, 12, 3. Later the patient's color improved and became slightly pink. It nursed well but two clyses, each 50 cc. of 5 per cent glucose in isotonic solution of sodium chloride, were given at 10 a. m. and 4 p. m. The infant continued to improve and was discharged from the hospital five days later weighing 7 pounds 7½ ounces (3,390 Gm.). On leaving the hospital the baby still showed a faint grayish tinting of the skin.

By stating that this case was a typical one, we do not intend to imply that the therapy was the same for each of the remaining 16 babies. It must be borne in mind that the infants were treated by their individual doctors as they saw fit, but a more or less general plan was followed.

DIFFERENTIAL DIAGNOSIS

Because of the rarity of aniline dye intoxication in nurseries the diagnosis is seldom thought of when extremely pronounced and unexpected cyanosis appears. Cyanosis in the newborn or young baby may often bring to mind various congenital heart malformations. Many men have associated enlargement of the thymus gland with cyanosis. Two of the commonest causes of cyanosis to be encountered in the infant are pneumonia and aspiration. Aspiration of a foreign body could be milk curds, mucus, mechanical objects and the like. Intracranial hemorrhage, common poisons such as sulfonamides, nitrites or ferrous cyanide, allergies from insect sprays or disinfectants and the escaping of illuminating gas often are first noticed because of the peculiar grayish blue tint that occurs as one of their early symptoms.

In this series of cases food was considered as the causative agent for only a short time in the beginning. It was found that all of the babies, whether breast fed or artificially fed, were affected similarly by the then unknown cause. Even babies who were brought directly from the delivery room and who received nothing by mouth developed the condition within a short time.

TREATMENT

In the Touro incident treatment centered around the use of methylene blue, oxygen and 5 per cent carbon dioxide and whole blood transfusions. Of the total number, 17, 12 infants were given methylene blue in the dosage of ½ grain (5 cc.) in each of their feedings for two days. All were fed by a three hour schedule. This left 3 babies that did not receive the methylene blue. The oxygen and 5 per cent carbon dioxide was given to 6 and blood transfusions to 9. Each of the 4 babies that died, except the premature twins, was given the same treatment. Transfusion was found to be too difficult a procedure on them.

Methylene blue and oxygen had no apparent effect on the time or type of recovery of any of the infants. Just as complete and just as speedy a recovery was seen in the 3 infants who had no treatment other than change of diapers, isolation and transfusion. Even in 2 of the infants who received no therapy whatever recovery was similar and uneventful. Had the diagnosis been apparent at the time, no treatment other than transfusion would have been tried. It has never been proved whether methylene blue has any effect on accelerating the rate of reduction of methemoglobin to hemoglobin, and in high concentration it converts the ferrous iron of reduced hemoglobin to reduced iron, thus producing methemoglobin. The use of oxygen in treating cyanosis of this type is not rational, since the methemoglobin reduces the amount of hemoglobin that can act as a respiratory pigment.

It is needless to say that the treatment lies first in the prevention, then in removing the source, transfusions with whole blood or red cells suspended in saline solution, giving plenty of fresh air and, finally, isolation. In a very profound case of cyanosis due to aniline, transfusions of whole blood or red cells suspended in saline solution would be the most logical therapeutic agent to use.

CONCLUSION

1. In 17 cases of aniline dye poisoning in a nursery the intoxication was caused by diapers stamped with ink containing aniline dye. Thirteen babies recovered; 4 died from unrelated causes.

2. The prevention of this type of poisoning rests in the adherence of a strict aseptic technic in handling all supplies entering the nursery. If this is done an ink-containing aniline dye could be used, as it becomes innocuous after the first laundering.

3. It must be remembered that only small proportions of aniline dye are necessary to produce intoxication in infants. This is true also for adults.

4. Treatment consisted primarily in removing the source of intoxication, oxygen and 5 per cent carbon dioxide, transfusion, methylene blue and isolation. Methylene blue and oxygen therapy were found to be unnecessary, and transfusions are not imperative unless the condition is acute and severe.

THE USE OF HUMAN IMMUNE SERUM GLOBULIN (GAMMA GLOBULIN)

IN INFECTIOUS (EPIDEMIC) HEPATITIS IN THE MEDITERRANEAN THEATER OF OPERATIONS

II. STUDIES ON TREATMENT IN AN EPIDEMIC OF INFECTIOUS HEPATITIS

CAPTAIN SYDNEY S. GELLIS
MEDICAL CORPS, ARMY OF THE UNITED STATES

JOSEPH STOKES JR., M D.
PHILADELPHIA

MAJOR H. WALTER FORSTER JR.

MAJOR GEORGE M. BROTHER
AND
MAJOR WILLIAM M HALL
MEDICAL CORPS, ARMY OF THE UNITED STATES

Because of the long period of convalescence following infectious hepatitis with resulting loss of manpower to the United States Army, the present study was conducted in suitable groups in the Mediterranean Theater of Operations in order to determine whether or not gamma globulin is an effective therapeutic agent in lessening the severity of the disease and in shortening the period of convalescence. Stokes and Neefe,[1] pointing out that globulin is often of value if injected soon after the onset of the initial symptoms of measles,[2] suggested its trial as a therapeutic measure in early infectious hepatitis.

Through the cooperation of an air force in this theater, patients developing infectious hepatitis were made available for the study. The majority of the patients came from one bombardment group and were diagnosed by the squadron physicians, who had extensive experience with the disease. Patients were chosen for the study as soon as possible after the onset of symptoms and signs suggestive of early, preicteric infectious hepatitis. Typical symptoms consisted of an acute onset of fever, chilliness or chills, headache, nausea, vomiting, anorexia and abdominal pain. Suggestive signs consisted of right upper quadrant tenderness and spasm, often with a palpable and tender liver. If there was any suggestion of scleral icterus, the patient was not included in the series. Alternate patients arriving at each squadron or headquarters dispensary were given 0.3 cc. of gamma globulin per pound of body weight. The average total dose of globulin was 45 cc., half of which was injected into each buttock. The only reaction consisted of pain and tenderness at the site of injection owing to the distention caused by the large dose administered. The pain was much less pronounced if the globulin was injected after the patient had been hospitalized and muscular movement thus limited. However, the globulin was administered as soon as a tentative diagnosis of early, preicteric hepatitis was made. The injected and control patients were evacuated from the dispensaries as soon as possible by plane to the 26th General Hospital in order to maintain a uniform program of clinical and laboratory follow-up of the group. It was understood that, in the attempt to diagnose hepatitis so early in the course of the disease, errors would be inevitable and patients with diseases other than infectious hepatitis would be included. However, it was felt that such cases would fall equally into the injected and control groups and could subsequently be discarded.

A total of 278 patients were admitted to the study; 70 of these developed jaundice subsequent to the time of injection of globulin. The great majority of the remaining patients proved to have hepatitis without jaundice, as indicated by the liver function tests and the subsequent course of the disease.

Before reviewing the hospital course of the injected and control patients, it appeared that the following criteria might be of value in determining whether or not globulin had an attenuating effect on infectious hepatitis once the disease had started: (*a*) the incidence of jaundice occurring in the injected and control groups, (*b*) severity and duration of jaundice, (*c*) length of hospitalization, (*d*) the duration of the period in which various laboratory tests showed activity of the disease and (*e*) the frequency of relapse in the two groups.

On the basis of the foregoing criteria the following results were obtained:

(*a*) *Incidence of Jaundice in Injected and Control Patients.*—Of the 70 patients who developed jaundice subsequent to admission to the study, 31 had received globulin and 39 were control patients. The difference between the two groups is not sufficiently great to be significant.

(*b*) *Severity and Duration of Jaundice.*—The severity and duration of jaundice proved to be unsatisfactory criteria for judging the attenuating value of globulin, as their variation within each group was so great. Cases with mild and transient jaundice fell equally into the injected and control groups.

(*c*) *Length of Hospitalization.*—Subjective symptoms determined to a great degree the length of hospitalization necessary in this disease, and since these were appreciably affected by the patient's desire or unwillingness to return to his unit it was impossible to use the period of hospitalization for comparison.

(*d*) *Length of Time in Which Laboratory Tests Indicated Activity of Disease.*—The only test which was conducted daily for each of the patients and could therefore be accurately compared in the two groups was the methylene blue test.[3] The average duration of a positive methylene blue test, counting from the first day of scleral icterus, was ten days for the injected patients and 9.9 days for the controls. Since the cephalin cholesterol flocculation test and the sulfobromophthalein test were not performed at identical intervals for all patients, the time required for these to return to normal could not be accurately determined for the two groups. Therefore the methylene blue test, the only test permitting comparison of the injected and control patients, revealed no evidence in favor of an attenuating effect of globulin.

(*e*) *Frequency of Relapses.*—Four patients in the control group and 1 in the injected group developed relapse of the disease. Since the total number of

This work was carried out under the direction of the Commission on Measles and Mumps of the Army Epidemiological Board, Preventive Medicine Service, Office of the Surgeon General, U S. Army.
The gamma globulin used in these studies was obtained from pools of plasma, each pool representing 3,000 to 5,000 individuals, collected by the American Red Cross and fractionated, according to the method of Cohn and his co-workers, by various biologic manufacturers These pools were obtained originally from groups of individuals in the Eastern and Southern regions of the United States.

patients with relapse is so small, this difference does not appear to be significant.

It was difficult to compare the cases of hepatitis without jaundice in the treated and control groups. Variation in the severity and duration of this form of the disease was even more evident than in hepatitis with jaundice. No clearcut evidence was obtained indicating an attenuation in the treated group.

COMMENT

In accordance with observations recorded in the majority of virus diseases that homologous immune bodies rarely are effective therapeutically when the symptoms have fully developed, immune bodies also in this epidemic disease appear to have little, if any, therapeutic value. As the present data do not include a large number of cases at their earliest onset, it is still possible that larger amounts of immune bodies in the form of gamma globulin or, more properly, gamma globulin from pools of convalescent plasma may prove effective in therapy. The obvious difficulty in obtaining cases of this disease at their earliest onset is very great and renders the possibility of such a therapeutic approach highly problematic.

The additional possibility that gamma globulin may be of value in the prevention of relapses or recurrences of the disease deserves further investigation.

SUMMARY

A program designed to test the effectiveness of human immune serum globulin (gamma globulin) in the attenuation of infectious hepatitis was conducted in an air force in the Mediterranean Theater of Operations.

Gamma globulin, 0.3 cc. per pound of body weight, was administered intramuscularly to alternate patients presenting the earliest symptoms suggestive of infectious (epidemic) hepatitis.

No evidence was obtained in the patients studied in favor of an attenuating effect of gamma globulin when administered early in the course of the disease.

Clinical Notes, Suggestions and New Instruments

PENICILLIN THERAPY IN PYLEPHLEBITIS

KENNETH E. GAMM, M.D., CHICAGO

Pylephlebitis is an inflammation of the portal vein caused by an acute suppurative process in that part of the abdomen drained by the portal vein. The disease carries a high mortality because of the multiple embolic liver abscesses arising from the infected thrombi in the portal system.

The most common condition causing this disease is acute appendicitis; however, gangrenous cholecystitis, infected thrombotic hemorrhoids, diverticulitis or pelvic suppuration may precipitate a portal thrombosis.

The case reported here followed an acute attack of appendicitis, so I shall confine the discussion to this disease.

In 1897 Armstrong[1] reporting in England, stated that this complication caused 5 per cent of the deaths due to appendicitis. Hawkes[2] in 1938 analyzed a series of 1,463 cases of acute appendicitis in which portal thrombosis occurred but 12 times. This lowered incidence can be attributed to earlier operative intervention in acute appendicitis.

From the Surgical Service, U. S. Marine Hospital, Chicago.

1. Armstrong, G. E.: Introduction to a Discussion on Appendicitis, Brit. M. J. **2**: 945, 1897.
2. Hawkes, S. L.: Thrombophlebitis of Appendical Vein, Surg., Gynec. & Obst. **66**: 62, 1938

PATHOLOGY

According to Crossland[3] pylephlebitis usually follows pronounced appendical disease. Busch and Spivack[4] reported 4 fatal cases in a series of 635 cases of acute appendicitis. Two of these were gangrenous appendicitis with perforation, and 2 were appendical abscesses. This fulminating type of appendicitis is usually attributed to the streptococcus. Early in the disease a septic thrombus is found in the terminal branches of the ileocolic vein, and if the thrombus is not removed at time of operation with the appendix the thrombus extends upward or breaks off and lodges in the liver. Early in the disease positive blood culture is rare. Later, when the liver is riddled with abscesses and its venous system is thrombosed, they may be obtained. Empyema of the right chest by direct extension from the liver may occur. Jaundice due to liver destruction is a late finding. Ascites is common and is associated with the massive portal obstruction.

SYMPTOMATOLOGY

In addition to the clinical history suggesting appendicitis, the patient may have a chill. Colp[5] found a chill in 6.8 per cent of his cases and Kelly and Hurdon in 15 per cent of theirs. Temperature elevations are out of proportion to the amount of appendical disease. Severe prostration accompanies even the milder cases of thrombophlebitis of the appendical vein.

TREATMENT

Prophylaxis by early removal of the appendix when inflamed is mandatory. Probably few cases would develop if all cases should come to operation during the first twenty-four hours.

Treatment by ligation of the veins in the ileocolic angle has been most disappointing. Wilms[6] first suggested this, and his operation was modified by Braun.[7] Routine ligation of the ileocolic vein is to be condemned, but all should be inspected and ligated if thrombosed.

Sulfanilamide has been used with success in 2 cases as reported by Ottenberg and Berck.[8]

REPORT OF CASE

History.—H. H., a man aged 22, a seaman, admitted June 2 1944, complained of dull pain in the right groin and a swollen abdomen. The patient had an operation for appendicitis, gangrenous type, done Feb. 10, 1944, This operation was done as an emergency measure at a hospital along the Florida coast He was transferred to the Marine Hospital in Chicago on June 2, 1944. The history forwarded with the patient stated that on Feb. 10, 1944 the patient presented himself with the typical signs and symptoms of acute appendicitis and was given an immediate operation. The appendix was suppurative with exudate on its outer surface; there were local peritonitis and a turbid peritoneal fluid. Cultures were not made. During the patient's convalescence he developed drainage from the wound but it healed after about three weeks. On the second postoperative day the patient developed chills and a septic temperature began; that is, he had an afternoon elevation with temperatures running to 101 and 102 F. and chills nearly every day. The white blood cell count was elevated to about 18,000 but the blood cultures were repeatedly negative. The patient had no particular complaints except anorexia and extreme weakness He perspired freely and subsequently developed an anemia which was treated with iron and blood transfusions. On April 24 he complained of shortness of breath and fulness of the abdomen; fluid was demonstrated in the right chest. This was subsequently aspirated. The first specimen was slightly turbid and in appearance was serosanguineous. Repeated aspiration a few days later revealed that the specimen was more purulent, was bile stained and had a peculiar odor which is usually associated

with a colon bacillus infection. At this time a diagnosis of pylephlebitis or thrombophlebitis of the portal veins, with liver abscess, was made. The patient developed a transitory jaundice, the liver became definitely enlarged and the patient became weaker. He was put on sulfanilamide therapy, 1 Gm. being given every four hours, and penicillin. A total of 10,000 units of penicillin was given before the patient was transferred to our hospital.

On admission, June 2, the patient had some pain in the abdomen and pain in his right groin. He had little appetite and felt weak. He was not taking sulfonamide drugs at this time but was on a high vitamin diet. The pain in the abdomen seemed to remain stationary in the right side but at times appeared to radiate toward the midline and down the right leg. The site of the operation did not pain him at that time. However, he felt "full in the abdomen" and was sure that he contained a lot of fluid. He had no pain in the right chest and had no dyspnea on exertion. He was slightly constipated and had to take liquid petrolatum to keep his bowels open. He had no dependent edema nor any pain or swelling in the legs which would indicate phlebitis of the femoral or iliac veins. A systemic review of his symptoms was noncontributory except for his present complaints.

His past history was noncontributory.

Physical Examination.—The patient was poorly nourished but fairly well developed and appeared acutely ill. There was evidence of great weight loss. He was too sick to weigh at this time but he stated that he had lost about 60 pounds. The eyes, ears, nose and throat were essentially normal. The ribs were prominent; the supraclavicular and infraclavicular fossae were depressed. There was limitation of excursion right and left, especially anteriorly. There was dulness to percussion in the left base, but in the right base the dulness was more evident and extended to the level of the nipple line anteriorly and to the level of the sixth rib posteriorly. There was no excursion of the diaphragm on the right. There were bronchial and vesicular breath sounds, right and left, with the breath sounds diminished in the bases. There were no rales audible. Tactile and vocal fremitus were diminished. There was tenderness over the posterior right lumbar area on Murphy's percussion. The heart was normal except for a roughened first sound. The pulse rate was 120, the blood pressure 125/80. The pulse, while rapid, was regular and of good quality. The abdomen was greatly distended and a fluid wave elicited. There was some shifting dulness but with so much fluid it was hard to demonstrate. The liver was enlarged 3 fingerbreadths below the costal margin, but it was smooth and some tenderness was present. The genitourinary examination gave essentially normal results. There were some muscle aches and pains in the extremities and in the joints on extreme ranges of motion. There was 1 plus edema over the dorsum of the feet. The temperature on admission was 38.2 C. (100.7 F.), the pulse rate 118.

Laboratory Work on Admission.—Red blood cells numbered 3,350,000, white blood cells 10,500; hemoglobin was 61.4 per cent, 9.5 Gm.; small mononuclears 22, stabs 34, neutrophils 41, 1 Türk cell, an occasional target cell. The urine was amber color and showed a trace of albumin; the specific gravity was 1.014. The Wassermann and Kahn reactions were negative; blood culture showed no growth after ten days; the icterus index was 10 units; the blood was of type O. Serum protein was 6.8 Gm. per hundred cubic centimeters of serum. Repeated blood cultures were negative. Repeated examinations of stools for parasites were negative for Endameba histolytica. X-ray examination at time of admission revealed a large liver with elevation of the right diaphragm.

Course.—The patient was observed for four days after admission and given a high protein, high vitamin diet with iron therapy. During that time he had temperature elevations that ran from 39 C. (102.2 F.) in the afternoon to 37.6 C. (99.7 F.) in the morning. On June 6 a soft area was noticed on the posterior chest wall at the level of the tenth rib, in the posterior axillary line. Under nitrous oxide anesthesia this soft mass was incised and drained. The pus was thick and green and had the appearance of concentrated streptococcus pus. The abscess cavity extended about 12 cm. in all directions and went beneath the latissimus dorsi deep to the tenth rib. We were unable to demonstrate any connection with the liver or with the subdiaphragmatic space. The pus was cultured both aerobically and anaerobically. Guinea pig inoculation for tubercle bacilli was negative; aerobic cultures were negative, but we were able to demonstrate anaerobic staphylococci on culture. Consequently the patient was placed on penicillin therapy, receiving 20,000 units intramuscularly every three hours until 2,000,000 units had been given. The patient had repeated aspirations of the abdomen while in the hospital so that we could control the amount of abdominal fluid. These aspirations were done about every five days, and approximately 1,500 cc. of ascitic fluid would be removed at each time. The patient continued to have low grade spiking temperatures, after the incisions and drainage of the abscess of the right chest wall, until June 27. At that time an aspiration of the liver was done in the posterior axillary line below the level of the twelfth rib so that we would remain retroperitoneal and outside of the pleural space. On June 27 an abscess of the liver was demonstrated; it contained about 100 cc. of thick greenish yellow purulent material and also contained much cellular débris. There was a slight putrefactive odor not characteristic of any organism. It was sent to the laboratory, and again an anaerobic staphylococcus was demonstrated. The abscess was then irrigated with saline solution and the washings were sent to the laboratory and a search made for amebas. None were demonstrable here, just as none had been demonstrable in the repeated stool examinations. Into the abscess cavity was injected 25,000 units of penicillin dissolved in distilled water. Repeated explorations were then made, but we were unable to demonstrate any more abscesses in the liver. Roentgenograms were made on several occasions after 100 cc. of air had been placed within the liver abscess; thus we were able to demonstrate that the abscess was in the liver and not in the subdiaphragmatic space.

The patient continued to improve; his anemia became less pronounced and the abscess of the liver was repeatedly aspirated. On June 30 we again opened the posterior wound in the right chest wall and demonstrated a connection between the abscess of the right posterior chest wall and the liver. Several Penrose drains were inserted deep into the chest wall and into the fistulous tract leading to the liver. This wound was also irrigated with a penicillin solution. On June 30, after we had drained the liver abscess, the patient became afebrile and continued so throughout the rest of his stay in the hospital. On July 8 lipiodol was injected into the fistulous cavity leading to the liver, and x-ray consultant Dr. J. T. Case interpreted the films as showing a large liver abscess which permitted the lipiodol to be demonstrated over a wide area, or perhaps as a liver abscess with numerous pockets in the abscess.

Recovery was very slow, owing to the fact that the patient had anemia and a severe debilitating disease. He was discharged from our hospital on September 19 as improved. He has returned as an outpatient several times since then and at present is able to return to work. He was last seen at this hospital in February 1945, at which time his weight was almost up to his normal of 190 pounds (86 Kg.). He was moving about as well as ever, felt energetic and was given a fit for duty certificate so that he could return to sea. His posterior right thoracic wound, through which the liver abscess was drained, was healed with a nontender adherent scar and he said that he had no abdominal pain, and his abdomen was not distended. At the time of discharge the red blood cell count was 4,850,000, with hemoglobin 90.4 per cent, 14.0 Gm. The white corpuscle count was 10,750, with 51 per cent neutrophils; 35 per cent stabs giving a total of 86 per cent polymorphonuclears, 12 per cent mononuclears and 2 transitional cells. There was a moderate toxic granulation of the polymorphonuclears. There was a tendency for the red cells to be of a hypochromic type. At the time of discharge the urine had a specific gravity of 1.022

and was negative for albumin, sugar, pus, casts or epithelial cells. He was advised to report for follow-up examination in six months.

SUMMARY

Pylephlebitis follows pronounced appendical disease and, while infrequent, should be considered when systemic symptoms are severe.

Thrombosis of the appendical vein may be a progressive disease, with extension into the portal vein, and result in multiple liver abscesses.

After appendicitis is diagnosed, chills, fever and prostration are the cardinal signs of this disease

Treatment is early operation, early ligation of the thrombosed ileocolic vein. If the disease progresses in spite of this treatment, chemotherapy with sulfadiazine and penicillin should be instituted.

A case of pylephlebitis ended in complete recovery.

A MEANS OF INDUCING OLIGURESIS DURING PENICILLIN ADMINISTRATION

ROBERT LICH JR., M.D., LOUISVILLE, KY.
Surgeon (R), U. S. Public Health Service detached to the U. S. Coast Guard with the rank of Lieutenant Commander

In reference to the published material suggesting the advisability of urine concentration in the penicillin therapy of gonorrhea, the following suggestion is made Pitressin to accomplish this end was suggested to me during observations on pitressin and its influence on human urine secretion. Because of the paucity of clinical material and facilities at sea the suggestion is passed on for evaluation by those more favorably situated for such study.

The antidiuretic principle of posterior pituitary was first noted by von den Velden[1] in 1913.

Gargle, Gilligan and Blumgart[2] in 1928 showed that it was the pressor function of the posterior pituitary that was responsible for the hormone's antidiuretic principle.

Leberman[3] in 1930 made use of this fact by employing the hormone to produce urinary concentration in the execution of renal concentration tests

McQuarrie and his associates[4] in 1936 used the period of diuresis which follows prolonged antidiuresis with pituitary to relieve edema in certain instances of nephrosis.

Lich and Lewis[5] have utilized pitressin induced antidiuresis to eliminate the period of water deprivation preceding intravenous pyelography.

In studying the effect of pitressin in normal man both during increased water intake and in normal conditions it was found that antidiuresis is maintained from three to five hours following the subcutaneous administration of 0.5 cc. of pitressin. This effect may be prolonged with the repeated administration of pitressin at intervals of three hours and may be continued for a twenty-four hour period. Hence this would seem a simple positive method to affect urinary concentration if this is essential in penicillin medication for the treatment of gonococcic urethritis.

SUMMARY

The use of pitressin subcutaneously is suggested to produce oliguresis during periods of penicillin therapy. It has been suggested in the literature that urinary concentration is beneficial in penicillin therapy of gonococcic urethritis.

NEW DOSAGE FORMS OF PENICILLIN

STATEMENT CONCERNING CERTIFIABLE PENICILLIN PRODUCTS, INCLUDING RECOMMENDED INDICATIONS, DOSAGES AND PRECAUTIONS

CHESTER S. KEEFER, M.D.
Chairman of the Committee on Chemotherapeutics and Other Agents of the National Research Council and Medical Administrative Officer to the Committee on Medical Research of the Office of Scientific Research and Development
BOSTON

ROBERT P. HERWICK, PH.D., M.D.
WALTON VAN WINKLE JR., M.D.
AND
LAWRENCE E. PUTNAM, M.D.
U. S. Food and Drug Administration
WASHINGTON, D. C.

On July 6, 1945 the Federal Food, Drug and Cosmetic Act was amended to provide for the certification of batches of drugs composed wholly or partly of any kind of penicillin. The Federal Security Administrator, in accordance with the provisions of this amendment, has promulgated regulations providing such standards of identity, strength, quality and purity as will insure the safety and efficacy for use of a number of penicillin products. Before distribution in interstate commerce, each manufacturer must submit samples of each batch of any penicillin product to the Food and Drug Administration for examination and must obtain a certificate showing that the batch complies with the applicable regulations.

Inclusion of the penicillin products listed in the regulations providing for certification was based on a review of the available scientific evidence and on information developed in consultations with experts in the field of chemotherapy and the medical and scientific staffs of interested manufacturers. The suggestions regarding indications, dosages and precautions reflect as closely as possible the experience of experts in penicillin therapy. These suggestions are necessarily conservative, since experience with many of these products has been limited and there are many questions yet unanswered. As additional evidence accumulates it may be possible to extend the indications and alter the dosage schedules set forth in the following paragraphs.

PARENTERAL PRODUCTS

SODIUM PENICILLIN AND CALCIUM PENICILLIN

Sodium penicillin and calcium penicillin are so purified and dried that the final products have a potency of not less than 500 units per milligram. They are sterile, nontoxic and nonpyrogenic and have a moisture content of not more than 2.5 per cent. They are packaged in 100,000 unit, 200,000 unit, 500,000 unit, 1,000,000 unit and 5,000,000 unit sizes.

Indications and Dosage.—

GROUP I INDICATIONS

1. All staphylococcic infections with and without bacteremia:
   - Acute and chronic osteomyelitis
   - Carbuncles—soft tissue abscesses
   - Meningitis.
   - Cavernous or lateral sinus thrombosis.
   - Pneumonia—empyema.
   - Carbuncle of kidney.
   - Wound infections—burns.
   - Endocarditis.

2. All cases of clostridia infections:
   Gas gangrene.
   Malignant edema.
3. All hemolytic streptococcic infections with bacteremia and all serious local infections:
   Cellulitis.
   Mastoiditis with intracranial complications, i. e. meningitis, sinus thrombosis and so on.
   Pneumonia and empyema.
   Puerperal sepsis.
   Peritonitis.
   Endocarditis.
4. All anaerobic streptococcic infections:
   Puerperal sepsis.
   Localized infections elsewhere.
5. All pneumococcic infections of:
   Meninges.
   Pleura.
   Endocardium.
   All cases of sulfonamide-resistant pneumococcic pneumonia.
6. All gonococcic infections.
7. All cases of anthrax.
8. All cases of chronic pulmonary suppuration in which surgical treatment is contemplated.
9. All meningococcic infections failing to respond to sulfonamides.
10. All cases of bacterial endocarditis due to susceptible organisms.
11. Erysipeloid (swine erysipelas).
12. Vincent's infection.
13. Prophylactic use in prevention of possible secondary infection following tonsillectomy and tooth extraction in cases with a history of rheumatic fever or in rheumatic heart disease, in congenital heart disease and in other conditions in which secondary infection may occur (infected teeth; tonsils).

GROUP II INDICATIONS

Penicillin has also been found to be an effective agent in the following diseases, but its position has not been definitely defined and will require additional experimental work:

1. Syphilis.
2. Actinomycosis.
3. Diphtheria, in conjunction with antitoxin.

GROUP III CONDITIONS OF QUESTIONABLE VALUE

Penicillin is of questionable value in mixed infections in which the predominating organism is of the gram negative flora—i. e.:

1. Ruptured appendix with peritonitis.
2. Liver abscesses.
3. Urinary tract infections due to Escherichia coli.
4. It is also of questionable value in rat bite fever due to Streptobacillus moniliformis.

GROUP IV CONDITIONS IN WHICH PENICILLIN IS INEFFECTIVE

1. All gram negative bacillary infections:
   Typhoid—paratyphoid.
   Dysentery.
   Escherichia coli.
   Hemophilus influenzae.
   Bacillus proteus.
   Bacillus pyocyaneus.
   Brucella melitensis (undulant fever).
   Pasteurella tularensis (tularemia).
   Friedländer's bacillus.
2. Tuberculosis.
3. Toxoplasmosis.
4. Histoplasmosis.
5. Acute rheumatic fever.
6. Lupus erythematosis, diffuse.
7. Infectious mononucleosis.
8. Pemphigus.
9. Hodgkin's disease.
10. Acute and chronic leukemia.
11. Ulcerative colitis.
12. Coccidioidomycosis.
13. Malaria.
14. Poliomyelitis.
15. Blastomycosis.
16. Nonspecific iritis and uveitis.
17. Moniliasis.
18. Virus infections.
19. Cancer.

Method of Preparing Penicillin for Treatment.—As penicillin is extremely soluble, it may be dissolved in small amounts of sterile distilled, pyrogen-free water, in sterile isotonic solution of sodium chloride or in sterile 5 per cent dextrose solution. When large unit sizes are being used in hospitals, the contents of the ampule should be dissolved in water or saline solution so that the final concentration is 5,000 to 50,000 units per cubic centimeter, depending on the circumstances of the case. This solution should be stored under aseptic precautions in the ice box and made up freshly every day. Solutions for local or parenteral use may be diluted further, depending on the concentration desired.

A. For intravenous injection:

1. The dry powder may be dissolved in sterile isotonic solution of sodium chloride in concentrations of 10,000 to 50,000 units per cubic centimeter for direct injection through a syringe.
2. The dry powder may be dissolved in sterile saline solution or 5 per cent glucose solution in lower dilution (25 to 50 units per cubic centimeter) for constant intravenous therapy.

B. For intramuscular injection:

1. The total volume of individual injections should be small, i. e. 10,000 to 50,000 units per cubic centimeter of isotonic solution of sodium chloride. It may also be given by constant intramuscular drip, 120,000 units in 250 cc.

Methods of Administration of Penicillin.—There are three common methods of administering penicillin—intravenous, intramuscular and topical. Subcutaneous injections are likely to be painful and should be avoided. The route of choice is intramuscular.

Dosage.—The dosage of penicillin will vary from one patient to another depending on the type and severity of infection. The objective in every case is to bring the infection under control as quickly as possible. In most cases a minimum of 100,000 units daily will be required.

It is well to remember that penicillin is excreted rapidly in the urine so that following a single injection it is often impossible to detect it in the blood for a period longer than two to four hours. It is well, therefore, to use repeated intramuscular or intravenous injections every three or four hours or to administer it as a continuous infusion.

A. In serious infections with or without bacteremia an initial dose of 15,000 or 20,000 Oxford units with continuing dosage as:

1. Constant intravenous injection of isotonic solution of sodium chloride containing penicillin so that 5,000 to 10,000 Oxford units is delivered every hour, making a total of 120,000 to 240,000 units in a twenty-four hour period. One half the total daily dose may be dissolved in a liter of isotonic solution of sodium chloride and allowed to drip at the rate of 30 to 40 drops per minute.
2. If a continuous intravenous drip is undesirable, 20,000 to 40,000 units may be injected intramuscularly every three or four hours.
3. After the temperature has returned to normal, the penicillin may be continued as long as there are any signs of active infection.

B. In chronically infected compound injuries, osteomyelitis and the like the dosage schedule should be 20,000 units every two hours or 40,000 units every four hours parenterally with local treatment as indicated. This dosage schedule may have to be increased, depending on the seriousness of the infection and the response to treatment. The best results are obtained in these cases when penicillin is combined with adequate surgical treatment.

C. Gonorrhea:

1. Twenty-five thousand units every three hours intramuscularly for five doses. The results of treatment should be controlled by culture of exudate. All patients failing to respond to the first course should be retreated.

D. Empyema:

1. Penicillin in isotonic solution of sodium chloride should be injected directly into the empyema cavity after aspiration of pus or fluid. This should be done once or twice daily, using 50,000 or 100,000 units, depending on the size of the cavity, type of infection and number of organisms. Penicillin solution should not be used for irrigation.

E. Meningitis:

1. Penicillin does not penetrate the subarachnoid space in appreciable amounts, so that it is necessary to inject penicillin into the subarachnoid space or intracisternally in order to produce the desired effect. Ten thousand units diluted in isotonic solution of sodium chloride in a concentration of 1,000 units per cubic centimeter should be injected once or twice daily, depending on the clinical course and the presence of organisms.

F. Bacterial Endocarditis:

1. Penicillin is the best agent available for the treatment of bacterial endocarditis. Penicillin alone is as effective as penicillin combined with heparin. The treatment should be continued for three weeks or longer, depending on the individual case. The intramuscular route is the one of choice, although in a few instances it may be desirable to use the continuous intravenous route in order to obtain the maximum effect. The dosage should range from 200,000 to 300,000 units a day if the best results are to be obtained.

PENICILLIN WITH DILUENT

Penicillin with diluent is a combination package of penicillin and a suitable solvent such as water for injection, 5 per cent dextrose injection or isotonic solution of sodium chloride.

Indications and Dosage.—Same as for sodium penicillin and calcium penicillin.

PENICILLIN IN OIL AND WAX

Penicillin in oil and wax is a suspension of calcium penicillin in a menstruum of refined peanut oil in which white wax is dispersed. It is packaged in 100,000 units per cubic centimeter, 200,000 units per cubic centimeter and 300,000 units per cubic centimeter concentration. The white wax content of the 100,000 units per cubic centimeter and 200,000 units per cubic centimeter concentrations is not less than 3 per cent and of the 300,000 units per cubic centimeter concentration not less than 4.7 nor more than 4.9 per cent. The calcium penicillin used in the 300,000 unit per cubic centimeter concentration has a potency of not less than 900 units per milligram, and that in the other concentrations has a potency of not less than 750 units per milligram.

Indications and Dosage.—Gonorrhea, acute staphylococcic and streptococcic infections and pneumonia.

All conditions require a minimum of 300,000 units per day. Preparations containing 200,000 units per cubic centimeter may be administered at twelve hour intervals. If the quantity is 100,000 units per cubic centimeter, administration at eight hour intervals is necessary. Rotation of the site of injection is desirable; the upper outer quadrants of the buttocks, the anterior thighs and triceps are suggested sites.

Gonorrhea.—Three hundred thousand units as a single injection or 200,000 units as an initial injection followed by 100,000 units in twelve hours, or three injections at eight hour intervals of 100,000 units each. In the presence of complications such as arthritis, endocarditis and epididymitis the dosage should be intensified and prolonged.

Pneumonia and Acute Staphylococcic and Streptococcic Infections.—A minimum of 300,000 units daily, preferably in divided doses and continued until the temperature returns to normal and other evidence of infection disappears.

Precautions.—DO NOT USE INTRAVENOUSLY. Do not use in those conditions listed in groups III and IV under "Sodium Penicillin" and "Calcium Penicillin."

ORAL PRODUCTS

TABLETS BUFFERED PENICILLIN, CAPSULES BUFFERED PENICILLIN

Tablets buffered penicillin and capsules buffered penicillin contain one or more of the buffer substances sodium citrate, citric acid, aluminum hydroxide, calcium carbonate, magnesium oxide and aluminum-dihydroxy-amino acetate. The potency of each tablet or capsule is not less than 20,000 units, and the number of tablets or capsules in each single package is such that the total number of units therein is not less than 300,000.

CAPSULES PENICILLIN IN OIL

Capsules penicillin in oil is a suspension of sodium penicillin or calcium penicillin in refined vegetable food oil. The potency of each capsule is not less than 20,000 units, and the number of capsules in each single package is such that the total number of units therein is not less than 300,000.

PENICILLIN WITH ALUMINUM HYDROXIDE GEL

Penicillin with aluminum hydroxide gel is a combination package of sodium penicillin or calcium penicillin and aluminum hydroxide gel. The quantity of aluminum hydroxide gel packaged with the penicillin shall be 30 cc. for each 100,000 units.

Indications and Dosage.—Oral penicillin preparations should be administered on a fasting stomach, not less than thirty minutes before or not less than one and one-half to two hours after eating.

Gonorrhea.—Combined Therapy: A single injection of 100,000 units followed not later than two or three hours by oral doses of 40,000 to 50,000 units each every two or three hours for six doses per day for one or two days.

Oral Therapy: Forty thousand to 50,000 units every two or three hours for six doses per day for one or two days.

In complications such as arthritis, endocarditis and epididymitis, administer penicillin parenterally. Concurrent infections of gonorrhea and syphilis should always be considered. Treatment of gonorrhea under the foregoing dosage schedule may prevent the appearance of the chancre and thus mask the first evidence of syphilis. The masking of the chancre should not be construed as a beneficial effect. Blood serologic tests should be made once a month for a minimum of three months.

Pneumococcic, Streptococcic and Staphylococcic Infections.—A minimum of 20,000 to 40,000 units of penicillin parenterally every three hours. After the acute phase and when the temperature has been reduced, treatment may be continued with oral administration. Treat with a dosage of 40,000 to 50,000 units each two or three hours (day and night) for at least forty-eight hours after the temperature has returned to normal. If the condition is not controlled by oral penicillin, return to parenteral administration.

Prophylaxis.—Against secondary infections after tonsillectomy or tooth extraction in cases with a history of rheumatic fever or rheumatic heart disease, congenital heart disease and other conditions in which secondary infections may occur (infected teeth or tonsils), administer 100,000 to 200,000 units daily in divided doses from one day before to three or four days after surgery.

Precautions.—In meningitis, endocarditis and peritonitis, administer penicillin *only* parenterally. In acute infection with bacteremia or septicemia, parenteral administration of penicillin should be continued until the blood cultures become negative and the acute condition is controlled. Do not use in those conditions listed in group III and IV under "Sodium Penicillin" and "Calcium Penicillin."

TOPICAL PRODUCTS

PENICILLIN OINTMENT; PENICILLIN OINTMENT OPHTHALMIC

Penicillin ointment is calcium penicillin in an ointment base composed of wool fat, petrolatum or white petrolatum, or any mixture of two or all of these with or without liquid petrolatum, white wax, yellow wax, cottonseed oil or peanut oil, or any mixture of two or all of these. Its potency is not less than 250 units per gram, and it contains not more than 50 viable micro-organisms per gram.

Penicillin ointment is packaged in collapsible tubes, not larger than 1 ounce size, except that ophthalmic ointments shall be in tubes not larger than the one-eighth ounce size.

PENICILLIN OINTMENT OPHTHALMIC

Indications and Dosage.—Superficial infections of the eye involving the cornea, conjunctiva, meibomian glands and lacrimal sac caused by organisms susceptible to penicillin. Apply one or more times a day as the condition indicates. Supplement local treatment of gonorrheal conjunctivitis with parenteral administration of penicillin.

Precaution.—If sensitization occurs, discontinue use.

PENICILLIN OINTMENT

Indications and Dosage.—Superficial infections of the skin caused by organisms susceptible to penicillin. Apply locally, with or without a bandage, one or more times a day as the condition indicates. If indicated, supplement local treatment with parenteral or oral administration of penicillin.

Precaution.—If sensitization occurs, discontinue use.

TOPICAL PENICILLIN

Topical penicillin is calcium penicillin which conforms to the standards prescribed therefor under "Calcium Penicillin" but is a fine powder. It may be packaged in vials or in foil enclosures containing not less than 10,000 units or not more than 50,000 units of penicillin.

Indications and Dosage.—For postoperative mastoid infections, inject through a small inlying catheter, directly into the cavity, 1 cc. of a sterile solution containing 50,000 units, once a day for a minimum of four days. In osteomyelitis, parenteral therapy may be supplemented by local instillation with 25,000 to 50,000 units in sterile solution two to three times a day. In empyema after aspiration, instil from 50,000 to 100,000 units into the cavity in a volume of solution less than the quantity of fluid aspirated. In superficial infections of the skin caused by organisms susceptible to penicillin, apply sterile dressings wet with a solution containing 1,000 units per cubic centimeter one or more times per day as the condition indicates. If indicated, supplement local therapy with systemic medication.

Precaution.—If sensitization occurs, discontinue use.

PENICILLIN TROCHES

Penicillin troches are composed of sodium penicillin or calcium penicillin and may contain masticatory substances. The potency of each troche is not less than 500 units. If the product contains masticatory substances, the word "chewing" or "masticatory" shall appear in juxtaposition with the name penicillin troches wherever such name appears on the label and labeling.

Indications and Dosage.—In Vincent's infection, allow one troche to dissolve in the mouth. Repeat two or three times a day between meals. Smears should be taken before and after therapy. If indicated, supplement local treatment with parenteral or oral administration of penicillin.

Precaution.—If sensitization occurs, discontinue use.

PENICILLIN TROCHES (MASTICATORY)

Indications and Dosage.—In Vincent's infection, chew two or three troches a day. When high continuous concentrations are desired, chew one troche each hour or two.

Precaution.—If sensitization occurs, discontinue use.

PENICILLIN DENTAL CONES

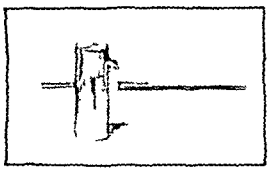
Penicillin dental cones are composed of calcium penicillin and may also contain sulfanilamide or sulfathiazole or both. The potency of each cone is not less than 500 units, and the content of viable micro-organisms is not more than 50 per gram. If a sulfonamide is used, its quantity is not less than 0.032 Gm. per cone.

Indications and Dosage.—Insert a cone after tooth extraction or as treatment for dry socket. Use in conjunction with parenteral therapy in operative procedures.

Precaution.—If sensitization occurs, discontinue use.

Awareness of Aging.—The subjective appraisal of failing physiologic and psychologic functions is largely an individual matter and is relative to cultural pressures and level of aspiration. Malamud points out that there is no one-to-one relationship between these different aspects of senile decline. Many of the psychologic traits of the aged are due to the cumulative effects of experience, to frustrations and the awareness of limitations, rather than to any primary or essential consequences of physiologic deficit.—Jones, Harold E., and Kaplan, Oscar J.: Psychologic Aspects of Mental Disorders in Later Life, from Mental Disorders in Later Life, edited by Oscar J. Kaplan, Stanford University Press, 1945.

Council on Physical Medicine



The Council on Physical Medicine has authorized publication of the following reports. HOWARD A CARTER, *Secretary.*

TORPIN INSUFFLATOR ACCEPTABLE

Distributors: University of Georgia School of Medicine.

This device is designed to aid in the resuscitation of the cyanotic newborn. It is essentially a combination of a liquid trap and safety valve. The pressure of oxygen or air administered to the infant's lungs is controlled at all times by the weighted valve, which blows off at 20 cm. of water pressure. The trap acts as a reservoir for aspiration of mucus and other secretions from the trachea and also as a trap for the expiratory secretions of the operator. A reprint of an article entitled "Apnea Neonatorum" by Perry P. Volpitto and Richard Torpin, submitted as part of the evidence, describes the instrument and explains how it is used.

The device was investigated in a laboratory acceptable to the Council. It was reported as a metal trap designed to be inserted between the lips of the physician and a tube in the infant's trachea. If one sucks on the device, the trap serves to keep one from sucking material into one's mouth, and the heavy lid on the trap will be raised if one blows with too high a pressure. This will prevent blowing up the infant's lungs unduly. If the physician attaches the appliance directly to a tank of oxygen under high pressure instead of to his mouth, it will allow oxygen to escape rather than let it go into the trachea under high pressure. This is a desirable safeguard. The apparatus is harmless in its potentialities. The insufflator has been manufactured for the University of Georgia, which so far has aided in its distribution.

Torpin Insufflator.

The Council on Physical Medicine voted to accept this product for inclusion in its list of accepted devices.

KREISELMAN RESUSCITATORS, ADULT CART MODELS, ACCEPTABLE

Manufacturer: The Ohio Chemical & Manufacturing Company, 1177 Marquette Street, Cleveland.

Kreiselman resuscitators are designed for the administration of artificial respiration with oxygen to patients whose spontaneous respirations have not been resumed. These models are primarily for use in medical institutions. Essential parts of the apparatus are a two stage automatic reducing valve and an adjustable automat for regulating the amount of positive pressure exerted at the face piece, a flowmeter calibrated for oxygen, a flowmeter control valve, a resuscitation inhaler and tubing. These units are mounted on an upright stand equipped with three wheels. The shipping weight is approximately 175 pounds. Only positive pressure is provided by the apparatus. There is no negative pressure developed at the face piece. The units come equipped with tools and instructions.

Kreiselman Resuscitator, Model 61-A.

Model 61-A, which is essentially similar to the others, was furnished for investigation. The Council investigator reported that the pressure regulator is standard for the company and is reliable. The fitting of the oxygen cylinder is made for a "commercial" cylinder, and an adapter is furnished to fit "medical" cylinders. The apparatus provides a pressure at the face mask varying up to 25 mm. of mercury. The gas is delivered by pressing on a convenient lever with the thumb of the hand which holds the face mask. The mask can be removed and a fitting for an endotracheal tube substituted. When attached to either mask or tube, double valves permit normal inspiration and expiration to take place through it when the inflation lever is not pressed.

A second mask receives oxygen through another tube by way of a standard Heidbrink flowmeter graduated up to 14 liters of helium-oxygen mixture or 11 liters of pure oxygen. This second mask is open around the oxygen inlet so that free respiration of air can take place with the mask held in place in case the flow of oxygen is inadequate.

Both the inflator and the inhalator are commendably safe since, if no oxygen is available, the patient can continue to breathe normally.

A motor with the air pump is mounted on the cart which provides adequate negative pressure to suck mucus from the throat of a patient. This part of the apparatus seems safe. Doubtless the motor and the pump are the best available at present. This apparatus complete will, it is believed, serve the purpose for which it is intended both safely and efficiently.

Other Kreiselman resuscitators are acceptable since they are variations in assembly of otherwise accepted parts. The parts are in different combinations. They are Models Nos. 52, 52-A, 52-B, 61, 61-A, 61-B, 80, 80J, 81 and 81J.

The Council on Physical Medicine voted to adopt the Kreiselman resuscitators, models aforementioned, for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

ALUMINUM HYDROXIDE GEL (See New and Nonofficial Remedies, 1944, p. 382).

The following dosage forms have been accepted:

BARLOW-MANEY LABORATORIES, CEDAR RAPIDS, IOWA

Aluminum Hydroxide Gel: 480 cc. bottles. Contains the equivalent of 3.6 to 4.4 per cent of aluminum oxide (U. S. P. XII).

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Aluminum Hydroxide Gel: 240 cc. and 3,840 cc. bottles. Contains the equivalent of 3.6 to 4.4 per cent of aluminum oxide (U. S. P. XII).

E. R. SQUIBB & SONS, NEW YORK

Aluminum Hydroxide Gel: 360 cc. and 3,840 cc. bottles. Contains the equivalent of 3.6 to 4.4 per cent of aluminum oxide (U. S. P. XII).

SYRINGE APPLICATORS FOR CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies, 1944, p. 341).

The following product has been accepted:

CONTRA CREME AND DIAPHRAGM CO., SEVERNA PARK, MD.

Contra Applicator: A transparent plastic syringe threaded at the blunt, intravaginal end, to screw onto the tubes of Contra Creme, to permit filling by compression of the tube. The full capacity is 5 cc., the recommended dose.

EPHEDRINE SULFATE (See New and Nonofficial Remedies, 1945, p. 270).

The following dosage form has been accepted:

THE WM. S. MERRELL CO., LOESER LABORATORY DIVISION, CINCINNATI

Solution Ephedrine Sulfate: 0.048 Gm. in 1 cc. ampuls.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1944, p. 417).

The following dosage form has been accepted:

WALLACE & TIERNAN PRODUCTS, INC., BELLEVILLE, N. J.

Tablets Diethylstilbestrol: 0.1 mg., 0.5 mg. and 1.0 mg.

SATURDAY, AUGUST 18, 1945

PENICILLIN IN SUBACUTE BACTERIAL ENDOCARDITIS

The therapy of subacute bacterial endocarditis, prior to the advent of the new chemotherapeutic agents, was all but futile. According to Libman, spontaneous recoveries probably occurred in from 3 to 5 per cent of the cases. Kelson and White [1] collected data on 66 cases treated intensively with sulfapyridine, and in 65 the course of the disease was not influenced by this therapy. Friedman, Hamburger and Katz [2] suggested that continued deposition of new fibrin and platelets on the vegetations created an impenetrable barrier to the action of otherwise effective agents; they proposed that a patient with bacterial endocarditis be first subjected to treatment with an anticoagulant such as heparin. Kelson and White [1] treated 7 patients with sulfapyridine and heparin. Only 3 patients were able to take heparin for more than a week, and in these there was a striking improvement. The first reports on the effect of penicillin in bacterial endocarditis were not encouraging. In the 17 cases reported by Keefer [3] there were four deaths during the course of treatment; in 3 cases temporary improvement was followed by a relapse in 2 soon after treatment was discontinued; no appreciable effect was noted in 10.

In contrast to these discouraging results, Loewe [4] reports a clinical cure in 75 per cent of a consecutive series of 54 unselected cases from a combined penicillin and heparin therapy. Loewe and his collaborators were able to limit the deposition of fibrin and platelets on the heart valves in animals with artificially induced bacterial endocarditis by administration of heparin. Friedman, McLean and others called attention to the difficulties and hazards of heparin therapy in man. Loewe and Rosenblatt [5] deposited the drug subcutaneously, utilizing the Pitkin menstruum, which is composed of gelatin, dextrose, glacial acetic acid and water in definite proportions. By this technic a slower and more equable absorption of heparin was accomplished. Loewe and his co-workers administered heparin and sulfonamide compounds combined to 17 patients with subacute bacterial endocarditis but could not determine an appreciable effect on the course of the disease in 15. Of the 54 patients treated with penicillin and heparin combined, 14 were failures and 40 appeared to be cured. In the latter group 37 are alive and many have resumed useful occupations; 3 have died of other causes. In the group of failures of treatment, thirteen deaths followed circulatory failure, coronary occlusion, embolization and pneumonia. These authors feel that a five week course of treatment with penicillin should be the standard minimum. Additional courses are well tolerated and are to be given when indicated. Based on penicillin sensitivity tests, an average daily dose of 200,000 Oxford units is suggested. Inadequate dosage invites failure, and the organisms may acquire resistance that is so high as to render future therapeutic levels unattainable. The total unitage in their series varied between the low 86,700 and a high of 48,930,000 Oxford units. To heparinize the blood effectually required subcutaneous deposition of 300 mg. of heparin every second or third day.

Dawson and Hunter [6] administered combined heparin-penicillin therapy to 16 patients with bacterial endocarditis. The infection of 11 patients has apparently been terminated. All 11 have remained bacteria free and in excellent health for three months or longer since treatment was discontinued. The infection of 2 patients was controlled but recurred when treatment was stopped. Two patients died as the result of a cerebral embolism. These authors feel that patients with subacute bacterial endocarditis should be treated with penicillin if the infecting organism is a streptococcus sensitive to the action of the drug. They were impressed with the advantages of administering penicillin by continuous intramuscular drip, as advocated by Harris.[7]

Bloomfield [8] and his associates obtained excellent results from intensive penicillin therapy alone carried on for six to eight weeks. All 11 patients were promptly made bacteria free except 1, who died early in the course of treatment. Eight were clinically cured of the infection after follow-up periods up to six months. One patient, apparently cured of the infection, died of cardiac failure. There were no clinical relapses or rein-

fections. These authors believe that the time factor is even more important than the daily dose. The failures of the early attempts were due to short periods of treatment. Continuous treatment over long periods is more likely to eradicate the infection than brief courses of penicillin.

CULTIVATION OF MALARIAL PARASITES

In 1912 Bass and Johns [1] reported a method for the cultivation of two species of malarial parasites of man. Blood drawn from a malarial patient was expelled directly into a defibrinating tube containing 0.1 cc. of a 50 per cent dextrose solution for each 10 cc. of blood taken. Defibrination was effected by gentle stirring with a glass rod. The defibrinated blood was allowed to sediment at incubator temperature (40 C.) until a column of serum ½ to 1 inch deep was above the sedimented cells. The parasites live and develop in the half millimeter top layer of the sedimented cells. All parasites beneath this top layer die and disintegrate. In such a culture the young parasites increase in size during the first twenty-four hours. Segmentation begins in about thirty-six hours. Extracellular parasites are rapidly ingested and destroyed by leukocytes. A free asexual malarial parasite cannot live longer than a few minutes in normal human serum. Probably, therefore, malarial plasmodia can pass from cell to cell only when the cells are in direct contact.

Most of the earlier investigators [2] who attempted to confirm this work reported that development of human malaria parasites in the so-called culture is at best only minimal. Counts show that increases do not occur in the number of parasites. Other investigators afterward applied a modification of this technic to the attempted cultivation of malaria parasites from canaries, domestic fowls and monkeys. Among the most favorable results were those reported by Gavrilov,[3] who showed that tissue cultures from the bone marrow of chickens infected with Plasmodium gallinacium remained infective for ten days. Trager [4] of the Rockefeller Institute effected in vitro survival of the bird malarial parasite (Plasmodium lophurae) up to sixteen days. The parasite population in his "cultures" usually remained constant for the first few days and then declined. He concluded that the death rate, particularly after the first few days, far exceeded the birth rate, though development must have been continuing in his preparations.

A much more successful in vitro cultivation of malarial parasites is now reported by Ball and his co-workers [5] of Harvard Medical School. They selected the erythrocytic form of Plasmodium knowlesi, a malaria parasite of monkeys (Macaca mulatta), which also produces infection in man. This parasite has a twenty-four hour asexual life cycle. They first developed a buffered nutrient fluid consisting of glucose (2.5 Gm. per liter), proteose peptone (1.5 Gm.), a purified mixture of amino acids (0.5 Gm.) and the usual salts necessary for tissue cultures, supplemented by presumably optimal amounts of all known essential vitamins.

Two culture technics were developed. By the first, or "rocker dilution," technic 1 part of whole malarial blood was added to 3 parts of nutrient fluid, and the mixture was placed in a flask equipped with a gas inlet and outlet. The container was placed in a rocker machine, which just kept the red cells in suspension. A slow flow of 5 per cent carbon dioxide in 95 per cent air was passed through the container. The whole procedure was carried out with aseptic precautions at a temperature of 38.5 C. The best results were obtained when the number of parasitized cells in the mixture was not more than 25,000 per cubic millimeter. More highly parasitized blood was diluted with several times its volume of normal monkey blood.

The second, or "rocker perfusion," technic employed a cellophane membrane to separate the infected blood from the nutrient medium. Several types of apparatus were developed. For small volumes of blood the cellophane membrane was stretched over one end of a glass tube about 1 inch in diameter. The blood was placed within the tube directly on the membrane. The tube was mounted in a vessel containing the nutrient fluid so that the membrane was just wet by the fluid. For larger cultures a coil of cellophane tubing was used. This was supported by a glass form and immersed in the blood. Nutrient fluid was allowed to flow through the tubing at a rate of approximately 1 cc. per minute. In both types of cultivation a slow stream of 5 per cent carbon dioxide in 95 per cent air was passed through the container, which was gently rocked to keep the corpuscles in suspension. All operations were performed at 38.5 C.

Cultivation was usually carried on for twenty-four hours. If subcultures were desired, a fresh setup was made at the end of each twenty-four hours, the parasitized blood being diluted with normal blood and the nutrient fluid replaced. The addition of one fourth volume of normal blood serum to the nutrient fluid was an advantage. In eighty-nine experiments the average increase in parasite count within twenty-four hours was approximately fourfold. In 60 monkeys the average in vivo increase in parasite count for the same period was also fourfold. Differential counts during the twenty-four hour period showed that segmentation usually takes place between the fifth and the tenth hour.

Under the rocker perfusion technic six successive generations have thus far been cultivated by the Harvard pathologists. The infectivity of the sixth genera-

tion was demonstrated by inoculation into a monkey. The technic is now being applied with encouraging results to the in vitro cultivation of human malaria parasites. Typical of results thus far obtained is their finding that para-aminobenzoic acid is probably the chief essential growth component furnished by the nutrient fluid. This in their opinion may help to explain the observation of Coggeshall [6] that sulfanilamide will eradicate P. knowlesi infections in monkeys.

UNAVAILABLE NUTRIENTS

After the discovery of the vitamins it became obvious that a conventional chemical analysis of a food might give little indication of its real nutritive value, as the relative quantities of these accessory food factors usually are too small to be thus measured. As time passed it became increasingly plain that a similar philosophy applies to dietary constituents which can be measured; in addition to a chemical analysis, the utilization of these constituents can be examined by the methods of biologic assay. Through this device it has been shown that a wide variation exists in the availability to the organism of dietary essentials in various forms in our foods. A relatively simple method of determining the availability of iron, for instance, is to measure hemoglobin regeneration in an animal on an iron free diet to which the source of iron to be tested is added. Sherman, Elvehjem and Hart [1] found that about 70 per cent of the iron of liver is available for hemoglobin formation but only 50 per cent of that in wheat can be used and only 20 per cent of the total iron of spinach is utilized. Nakamura and Mitchell [2] examined some pure iron compounds and found that the iron of ferric phytate was only about one half as available to the rat as ferric chloride. The presence of phytate is believed to explain the low utilization of the iron of whole wheat.

In studying the calcium utilization of high extraction flour, that is, the dark flour which contains most of the wheat kernel, McCance and Widdowson [3] observed that the calcium of 92 per cent extraction flour was less completely used by human subjects than was the calcium in 69 per cent extraction flour (white flour). Addition of sodium phytate to the white flour depressed the availability of calcium in the product. In a white flour to which dephytinized bran was added to simulate a synthetic high extraction flour, the calcium was as available as in the original white flour. Hence the factor in whole wheat which renders its calcium unavailable is believed to be phytic acid.

Earlier investigations have shown that both human beings and experimental animals are unable to utilize the thiamine from fresh yeast as completely as that present in dried or dead yeast samples. Recently Parsons, Williamson and Johnson [4] have presented data on human subjects which show that the thiamine present in two types of commercial bakers' yeast was not utilized when the yeast was fed in the fresh state. This was indicated by a high fecal and low urinary excretion of thiamine. In addition, ingestion of these yeasts reduced the availability of thiamine which was supplied by the basal diet. By boiling the yeast for a short time before ingestion, the availability of the thiamine present in the yeast cells was strikingly increased. Although a different species of yeast with a higher thiamine content did not show the inhibition of utilization of dietary thiamine, boiling this yeast also made its thiamine more available. Thus it appears that fresh yeast is not as reliable a source of thiamine as is heat-treated yeast.

Evidently the total content of a nutrient in a food is not the only index to its nutritional value; of equal or more importance is the ability of the animal to utilize the nutrient. Tables of nutritive factors in foods will no doubt soon give the available or utilizable nutrients rather than the total nutrients as shown by chemical analysis. Such tables would be especially valuable to the physician who is planning adequate therapeutic diets.

Current Comment

DIAGNOSIS OF PULMONARY TUBERCULOSIS IN THE ADULT

In a recent essay on primary principles for guidance in the diagnosis of tuberculosis of the lungs Pinner [1] emphasizes the need of a better understanding by the public of the possible significance of minimal symptoms and the importance of proper examination of the patient. In pulmonary tuberculosis, as also in cancer, the advanced stage of the disease when the patient comes under treatment is the greatest hindrance to its success. In both instances the fault may lie with the patient who fails to seek treatment early or with the physician who fails in his diagnosis. Pinner points out that periodic x-ray examination, which is the only means of discovering pulmonary tuberculosis in a prognostically hopeful stage, is not yet practiced as promptly and widely as its value demands. He urges more and wider x-ray surveys, especially in groups in which tuberculosis is prevalent. The preemployment examinations, including x-ray films, which have proved of great value in defense industries should be continued and followed by earnest efforts at physical and economic rehabilitation. The lack of such efforts is "probably the weakest link

in our present antituberculosis work." In his discussion of the actual diagnosis of pulmonary tuberculosis in a case Pinner makes it clear that the question is to determine whether or not an active tuberculous focus is present in the lungs. Here the value of the tuberculin test will depend on the reactor rate of the group to which the patient belongs. The test would hardly be worth while in cities where that rate is close to 100 per cent in adults. While the presence of a focus of disease in the lungs may be demonstrable by physical examination, physicians should remember that absence of a focus cannot be determined without proper x-ray examination. The patient cannot be assured that he does not have pulmonary tuberculosis except on the basis of such examination. Establishment that a focus in the lungs is actively tuberculous requires the demonstration of tubercle bacilli in the sputum or in the gastric contents. If bacilli cannot be found in the presence of a suspected focus, all the differential diagnostic possibilities must be considered. The demonstration of tubercle bacilli, changes on serial roentgenograms and pulmonary symptoms establish active tuberculosis, but the absence of any one of these criteria does not exclude activity. The decision may require prolonged observation. In recent years the examinations on military induction, before employment and in diagnostic surveys are bringing to light so-called asymptomatic patients in whom pulmonary lesions are discovered accidentally. Here the problem of differential diagnosis and tuberculous activity requires special study. In Pinner's hands serial roentgenograms, bacterial tests and close study of symptoms have given good results, while hematologic data have been of relatively low value In view of the fundamental importance of the x-ray examination in the recognition of pulmonary tuberculosis, provision should be made everywhere for competent free examination of patients who are unable to pay. Fortunately this is now done in many cities. The importance of early correct diagnosis cannot be overstated, because "symptomatic treatment without adequate diagnosis is a prominent cause of far advanced tuberculosis."

STAIRWAYS AND THE PHYSICALLY HANDICAPPED

The National Society for Crippled Children and Adults has recently inaugurated a campaign to construct new public buildings with ground level entries, elevators between floors and the elimination of all unnecessary steps. This society also urges the remodeling of existing buildings with long flights of stairs, to provide ground level entries, elevators, ramps and other practicable measures aimed at the elimination or amelioration of impediments to ready access. Patients with heart disease, crippling illnesses, missing limbs or other disorders of locomotion form an increasing proportion of the population, both because of the war and because of the lengthened average age. Progress along the lines suggested should decrease the number of accidents among the handicapped as well as greatly increase their ability to perform business activities and seek pleasure with greater frequency and ease.

THE SLOAN-KETTERING INSTITUTE FOR CANCER RESEARCH

In connection with the expansion of the Memorial Hospital in New York City the Alfred P. Sloan Foundation has announced the appropriation of $4,000,000 for the erection and initial maintenance of the Sloan-Kettering Institute for Cancer Research. The building will stand in the middle of the "Memorial Cancer Center." The cost of construction is estimated at $2,000,000, and $200,000 a year will be provided for running expenses for ten years. The clinical facilities and materials of the center will be available to the institute, which will have its own board of trustees and be "self contained in all its various research functions." The present research organization of the hospital will become part of the institute. To complete the plans for the expansion of the Memorial Hospital an additional $3,000,000 to $4,000,000 will be needed for increase of its bed capacity, for training fellowships and for the equipment of the James Ewing Hospital of 300 beds to be built by the city of New York on the same grounds. The completion of this program will result in the creation of a great center for cancer service and cancer research, a model for the establishment of similar centers in other cities. Commenting on the projected institute Mr. Alfred P. Sloan Jr., the sponsor of the foundation, said that his industrial experience has led him to appreciate the amazing possibilities of research when organized on a broad and comprehensive scale and that he and his associate, Dr. Charles F. Kettering, are convinced of the applicability of the broad principles of organized industrial research to the problems of cancer. "The current acceleration of scientific knowledge provides an unusual opportunity for a determined all-out effort." Mr. Sloan also said "In addition to this specific project we hope it may be possible to organize on a high scientific level the more complete coordination of other worthy efforts now being directed to the same end objective. It is of great importance that this be done. It should result in a more effective use of aggregate resources now available for the purpose." This is indeed tidings of momentous significance. Solution of the problems of cancer can be attained only by research. The new institute will carry on its work in the spirit and the conviction that long-range programs of research with adequate support and direction can solve such problems. At the same time the control of cancer by the means at hand will be steadily promoted by improving and enlarging the facilities for skilled clinical service coupled with continuous education of the public in the vital importance of early and effective treatment.

MEDICINE AND THE WAR

TRANSPORTABLE SICK AND WOUNDED SOLDIERS HOME FROM EUROPE

The War Department recently announced that the Army's plan for bringing all transportable sick and wounded soldiers home from Europe within ninety days after V-E day will be completed according to schedule. To achieve this ninety-day goal army authorities put on such pressure, beginning with V-E day, that the major portion of the task was done within sixty days. This is in sharp contrast to the procedure in the first world war, when American sick and wounded soldiers remained overseas about a year.

In May there were more than 43,000 soldiers brought home from the European theaters, practically all after May 8, or V-E day. With approximately 14,000 who came into West Coast hospitals, this brought the May total to an all time high of approximately 57,000 who were evacuated. The figure for evacuees from Europe dropped the next month to slightly less than 32,000, which, with the Pacific casualties, made the evacuation total over 42,000 for June. In July approximately 27,000 arrived at East Coast ports, which included practically all of those who were wounded prior to V-E day. The number of nontransportable cases is comparatively small, Brig. Gen. Raymond W. Bliss, assistant Surgeon General of the Army, said.

The nation's wounded and sick servicemen arrive under the care of army doctors, nurses and Medical Department personnel at New York, Charleston, S. C., Boston and Hampton Roads, Va. The majority are disembarked at the first two ports. It is only a matter of hours from the time these soldiers reach port until they are assigned a bed at a nearby hospital, such as Halloran General at New York or Stark General at Charleston.

At the time of Pearl Harbor there were approximately 15,000 beds in all army general hospitals in this country. The army general and convalescent bed capacity is now 215,000. This does not include the vast network of army station and regional hospitals which care for the routine needs of sick and wounded soldiers who have been incapacitated in this country.

CIVILIAN PSYCHIATRISTS COMPLETE ETO SURVEY

At the request of the Surgeon General, the Office of Scientific Research and Development appointed a group of noted civilian psychiatrists to undertake a study of combat exhaustion problems in the European Theater of Operations. These psychiatrists have now returned with a report of their findings. Included in the group which made the survey with the cooperation of the Army Medical Department are Dr. Leo H. Bartemeier, professor of psychiatry, Wayne University, Detroit; Dr. Lawrence S. Kubie, associate in neurology, Columbia University College of Physicians and Surgeons, New York; Dr. Karl Menninger, director of the Menninger Clinic, Topeka, Kan.; Dr. John Romano, professor of psychiatry, Cincinnati General Hospital, Cincinnati, and Dr. John C. Whitehorn, chief psychiatrist of Johns Hopkins Hospital and professor of psychiatry, Johns Hopkins University School of Medicine, Baltimore.

AWARDS MADE FOR YUGOSLAV TYPHUS WORK

Brig. Gen. Leon Fox, Birmingham, Ala., chief of the United States Typhus Commission, and three members of his staff were recently awarded the Yugoslav medal for services to the people of Yugoslavia. Two of the awards were given to Lieut. Col. Edward Murray, Cedar Rapids, Iowa, and Lieut. Col. Charles Wheeler, Doon, Iowa.

95TH STATION HOSPITAL AWARDED PLAQUE

The Meritorious Service Unit Plaque was recently awarded to the 95th Station Hospital "for superior performance of duty in the completion of exceptionally difficult tasks under adverse conditions and the maintenance of a high standard of military discipline and efficiency during the period Oct. 15, 1944 to Feb. 15, 1945." Col. A. A. Leonidoff is commanding officer of the hospital, and Major James W. Tobin and Lieut. Col. Charles D. Driscoll are chief of surgical service and chief of medical service, respectively.

DR. A. L. BENISON REPORTED MISSING

Dr. A. L. Benison, formerly of Edmore, Mich., serving in the U. S. Army and captured by the Japanese at Pearl Harbor, is reported lost on a Japanese prison ship 200 miles off the coast of China. The ship was reported to have been torpedoed by submarines as it was taking American war prisoners to Japan last October 24. Dr. Benison graduated from the University of Michigan Medical School, Ann Arbor, in 1937 and entered the service May 15, 1941.

ARMY AWARDS AND COMMENDATIONS

Colonel Clifford V. Morgan

A Bronze Oak Leaf Cluster to the Legion of Merit was recently awarded to Col. Clifford V. Morgan, formerly of Washington, D. C. The citation accompanying the award read "for exceptionally meritorious conduct in the performance of outstanding services, as deputy general purchasing agent, Forward Echelon, Headquarters Communications Zone, European Theater of Operations, from Feb. 25, 1944 to Aug. 7, 1944. Colonel Morgan supervised and coordinated general purchasing planning as far as coordination was necessary with 21st Army Group (British), First United States Army Group, First United States Army, Third United States Army, Western Task Force, 9th Air Force, and agencies of Communications Zone staff. He ably guided and facilitated purchasing planning for overseas operations and formulated a clear and concise general purchasing agent plan consistent with directives of higher authority. Colonel Morgan rendered outstanding services on the continent not only by advising and personally assisting the advance section, but also by attaching key personnel to that section for training purposes." Dr. Morgan graduated from the University of Nebraska College of Medicine, Omaha, in 1927 and has been in the service since August 1928.

Colonel Edward D. Churchill

The Legion of Merit was recently awarded to Col. Edward D. Churchill, formerly of Boston, "for exceptionally meritorious conduct in the performance of outstanding services. By instituting advanced principles of war surgery throughout American hospitals in the theater during the Tunisian campaign, and by initiating a standardized surgical technic, he was responsible to a considerable extent for the extremely low mortality rate among wounded soldiers. By his keen foresight, his efficient planning and careful supervision of surgical procedures, much suffering was alleviated and many lives were saved." Dr. Churchill graduated from Harvard Medical School, Boston, in 1920 and entered the service Jan. 10, 1943.

Major Donald Grillo

For his work in the activation and evacuation of his station hospital at Kweilin, China, Major Donald Grillo, formerly of Gary, Ind., was recently awarded the Bronze Star. Dr. Grillo graduated from Indiana University School of Medicine, Indianapolis, in 1929 and entered the service in July 1942.

Major Edward C. Dyer

The Bronze Star was recently presented to Major Edward C. Dyer, formerly of Boston, "for meritorious achievement in action during the period Feb. 19, 1945 to Feb. 25, 1945, near Monte Belvedere, Italy." Dr. Dyer graduated from Harvard Medical School, Boston, in 1939 and entered the service Feb. 17, 1942.

Major Harry DeWitt Nesmith

Major Harry DeWitt Nesmith, formerly of Salem, Ill., was recently awarded the Bronze Star for meritorious achievement in connection with military operations against the enemy from June 1, 1944 to March 31, 1945. At the present time he is stationed in Germany. Dr. Nesmith graduated from the University of Illinois College of Medicine, Chicago, in 1939 and entered the service in March 1941.

Major Hugh M. Crumay

The Air Medal was recently awarded to Major Hugh M. Crumay, formerly of Mercer, Pa. The citation accompanying the award read "For meritorious achievement while participating in the Southwest Pacific Area, during which hostile contact was probable and expected. The courage and devotion to duty shown during these fights are worthy of commendation." Dr. Crumay graduated from Harvard Medical School, Boston, in 1933 and entered the service July 17, 1942.

Captain David Paris

The Bronze Star was recently awarded to Capt. David Paris, formerly of Cushing, Okla., "for meritorious achievement in connection with military operations against the enemy at Aitape, British New Guinea, from July 1, 1944 to Sept. 9, 1944; at Morotai, Netherlands East Indies, from Sept. 15, 1944 to Nov. 9, 1944; at Leyte, Philippine Islands, from Nov. 14, 1944 to Jan. 22, 1945, and at Luzon, Philippine Islands, from Jan. 29, 1945 to June 1, 1945." Dr. Paris graduated from the University of Oklahoma School of Medicine, Oklahoma City, in 1941 and entered the service July 1, 1942.

Captain Robert L. Kendall

Capt. Robert L. Kendall, formerly of Ardmore, Okla., was recently awarded the Bronze Star "for meritorious service in direct support of combat operations from Aug. 15, 1944 to Jan. 15, 1945 in France. During this period Captain Kendall's station has operated under a variety of conditions ranging from rapid advances requiring a high degree of mobility to static conditions with a large number of casualties. Despite adverse circumstances, Captain Kendall obtained a high state of efficiency and standard of medical care. The problem of serving two additional regiments was handled promptly and efficiently under his direction." Dr. Kendall graduated from the University of Oklahoma School of Medicine, Oklahoma City, in 1940 and entered the service Jan. 6, 1942.

NAVY

THE NAVY MEDICAL OFFICERS INQUIRE ABOUT DISCHARGE

[NOTE.—*Recently a letter from five Army medical officers was published. Here follows a similar communication from five Navy medical officers.*—ED.]

To the Editor:—We are Navy medical officers on active duty for varying lengths of time ranging from forty-two to thirty months. Most of us have seen duty throughout the mid and southwest Pacific. Like our Army colleagues, we have given much thought to the problems of rotation and the staffing of veterans' hospitals after the war. We have two suggestions to make which we sincerely believe are practical and meritorious. Like our colleagues, we hope to be heard and we trust that you will publish this letter under conditions similar to those pertaining to the Army one.

There are hundreds of Navy reserve medical officers on active duty who are over 40 years of age and have served for over three years. Many of these are married and have families. Like firemen, they have been standing by their posts, often inactive for long periods of time. They are anxious to work and to use their medical skill where it is most needed.

There are hundreds of civilian physicians who are overworked, some of them for as much as fourteen hours a day, and have been overworked for several years. Without waiting for the cessation of hostilities, would it not be possible to have the Procurement and Assignment representative in each state relieve some of these overworked civilian physicians with relatively idle Navy medical officers? To effect the transfer in as close a location as was proper, Navy headquarters in each district could submit to P. & A. headquarters the names of reserve physicians over 40 years of age or who have had over three years' active service and who express a desire to be relieved. The civilian physician could be shown the ropes by one of the other Navy medical officers and, like many other civilian employees of the Navy, would not have to wear a uniform.

The staffing of larger temporary Naval hospitals and of veterans' hospitals after the war deserves grave consideration. A system similar to the foregoing could be adopted for a period of thirty-six months following the end of hostilities. Overworked civilian physicians could be assigned to such hospitals under a special classification by the state P. & A. director. (If civilians are strong enough to work extremely hard for twelve hours a day in private practice they will certainly be able to stand the less arduous duties of an eight hour day in a Naval or veterans' hospital; indeed, the change will benefit them.) It will be noted that this suggestion in no way interferes with the training of medical students, since it is not proposed that men essential for full time teaching be displaced. The basic proposal is for a fair rotation of civilian and military doctors for a three year period following the termination of hostilities; at the end of that time the matter can be reviewed and further equitable adjustments made.

MARINE CORPS' AMPHTRACKS EQUIPPED AS FIELD HOSPITAL

The Marine Corps' amphtracks are now fitted with the equipment of a field hospital and are serving as front line mobile operating rooms. Utilization of the hitherto strictly combat vehicle in its new role is the idea of Navy Capt. Joseph W. Kimbrough, formerly of San Francisco and now chief surgeon of the First Marine Division, who started work on the idea months before the invasion of Okinawa. Once the amphtrack moves into the desired site, the hospital gear is unpacked and set quickly into position. The metal interior is covered with white fabric, trays of surgical instruments are placed in a sterilizer and the portable operating table and lamp are set up. Then by means of the canvas covers carried as part of the regular equipment of the vehicle, blackout curtains are rigged so that the doctors can work throughout the night without fear of drawing enemy rifle or artillery fire.

HEAD OF POSTWAR PLANNING BOARD

Capt. William E. Eaton (MC), U.S.N. (Ret.), was recently relieved as head of the Washington Office, Materiel Division, Bureau of Medicine and Surgery, to devote full time to his duties as head of the Postwar Planning Board. Succeeding him in the materiel post is Lieut. Comdr. Paul T. Rees (HC), U.S.N., whom the Surgeon General also has nominated as representative of the Bureau of Medicine and Surgery to work with the logistics organization planning unit on the call of its senior member in the development of a Navy supply program.

COMMANDER EUGENE PERRY HARRIS

The Croix de Guerre with red star was recently awarded to Comdr. Eugene Perry Harris, formerly of Washington, D. C., by the government of France for exceptional war service rendered in the course of operations in the liberation of France for the period June to December 1944. Dr. Harris was previ-

ously awarded the Legion of Merit by our own government for his work during the same time interval. He is at present assigned to the U. S. Naval Hospital, Corvallis, Ore., as chief of the eye, ear, nose and throat service. Dr. Harris graduated from the University of Texas Medical Branch, Galveston, in 1930 and was commissioned in the Navy in January 1937.

NAVY AWARDS AND COMMENDATIONS

Lieutenant (jg) Leonard Hunter Roach

The Bronze Star was recently awarded to Lieut. (jg) Leonard Hunter Roach, formerly of St. Louis. The citation accompanying the award read "for heroic achievement as assistant battalion surgeon during action against enemy Japanese forces in the Marianas Islands, on Saipan from June 15 to July 10, 1944 and on Tinian from July 24 to Aug. 1, 1944. Courageous in the face of a heavy artillery and mortar barrage, Lieutenant, Junior Grade, Roach displayed outstanding professional skill and executive ability in evacuating casualties on the beach during initial landings on Saipan and, by his valiant devotion to duty during the invasion and occupation of these islands, continued to administer medical aid to wounded men, thereby materially reducing casualties under the extremely difficult combat conditions. His self-sacrificing spirit and gallant conduct were in keeping with the highest traditions of the United States Naval Service." Dr. Roach graduated from the University of Cincinnati College of Medicine in 1942 and entered the service May 3, 1943.

Lieutenant Frank Ashbrook Stewart

The Silver Star was recently awarded to Lieut. Frank Ashbrook Stewart, formerly of Stamford, Conn. The citation read "for conspicuous gallantry and intrepidity while serving with the 3d Battalion, 1st Marine Division during action against enemy Japanese forces at Cape Gloucester, New Britain, on Jan. 14, 1944. With his battalion engaged in routing a fanatic, deeply entrenched enemy from heavily fortified Hill 660, Lieutenant Stewart fearlessly risked his life in a valiant effort to aid marines who had fallen under the fierce opposition. Gallantly proceeding up the steep incline through enemy infested, unfamiliar jungle terrain, he skilfully and calmly cared for the wounded despite the enemy's shattering machine gun and rifle fire, carrying out his perilous task with undaunted initiative until evacuation could be effected. By his outstanding professional ability, determined perseverance and grave concern for the safety of others at great personal risk, Lieutenant Stewart contributed to the saving of many lives and upheld the highest traditions of the United States Naval Service." Dr. Stewart graduated from the University of Nebraska College of Medicine, Omaha, in 1940 and entered the service Feb. 8, 1943.

Lieutenant Commander Francis A. Agrest

Lieut. Comdr. Francis A. Agrest, formerly of Brooklyn, was recently awarded the Presidential Unit citation. Commander Agrest took part in three campaigns with the First Marine Division in the Southwest Pacific. He graduated from the Long Island College of Medicine, Brooklyn, in 1934 and entered the service March 29, 1941.

MISCELLANEOUS

EPIDEMICS OF RELAPSING FEVER

The extensive epidemics of typhus which swept North Africa during the war have been followed by an epidemic of louse borne relapsing fever. Dr. G. Stuart, chief of the Epidemic Control Section of the UNRRA European Regional Office, stated that more than 40,000 cases were reported up to March 1945, mainly in Tunisia, but in recent months the outbreak has spread also to Algeria and Morocco. After the first world war eastern Europe suffered from extensive epidemics of relapsing fever, and some twenty years ago this disease decimated the population of the semiarid country south of the North African desert belt. Lately there have been small outbreaks in southern France and in Rumania, but so far there has been no major epidemic in Europe.

UNRRA CONTRIBUTES FULLY EQUIPPED AMBULANCE

A fully equipped ambulance was recently turned over to the republic of San Marino by Lieut. Col. Vincent B. Lamoreux of the UNRRA Italian Mission Medical Division. This is the first contribution under the agreement signed recently with UNRRA whereby the small republic is to receive assistance up to $30,000. Medical supplies transported in the ambulance included penicillin, insulin, DDT insecticide powder, vitamin C tablets, ether, calcium gluconate ampules, phenobarbital tablets, sulfadiazine ointment, bandages, cotton gauze, suture catgut, syringes, thermometers, forceps, blankets, sheets, powdered and condensed milk, and sugar.

DDT ADDED TO INSECTICIDE MIXTURE

Addition of DDT to the Army's insecticide dispenser, known among troops in the Pacific as the aerosol bomb, has greatly increased the effectiveness of the insecticide mixture in that now it kills not only mosquitoes but also disease-bearing flies. The new mixture is composed of 85 per cent freon, 2 per cent of a 20 per cent pyrethrum solution, 5 per cent cyclehexanone, 5 per cent lubricating (hydrocarbon) oil and 3 per cent DDT. With DDT added, the aerosol bomb becomes an excellent weapon in the fight against malaria and fly-borne diseases.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

Birmingham General Hospital, Van Nuys: Effects of High Altitude and Gravity, Prof. D. R. Drury, September 12; Cardiovascular Problems, Dr. W. Gordon Garnett, September 26.

Camp Cooke Station Hospital, Lompoc: Respiratory Disease Problems, Major F. E. Willett, September 5; War Wounds of the Chest, Lieut. Comdr. J. P. O'Connor and Lieut. Henry Jaffee, September 19.

A. S. F. Regional Hospital, Camp Haan: The Pneumonias, Dr. W. E. MacPherson, September 4.

Hoff General Hospital, Santa Barbara: Respiratory Disease Problems, Major F. E. Willett, September 5; War Wounds of the Chest, Lieut. Comdr. J. O. O'Connor and Lieut. Henry Jaffee, September 19.

A. A. F. Regional Station Hospital, March Field, Riverside: The Use of Fibrin and *Fibrolysin* in Wound Healing, Capt. Harry P. Schenck, September 18.

Santa Ana Army Air Base Regional and Convalescent Hospital, Santa Ana: Acoustic Trauma, Comdr. D. G. Mitchell, September 4; Rheumatic Heart Disease, Dr. Louis E. Martin, September 18.

Torney General Hospital, Palm Springs: Surgery of the Biliary Tract, Capt. Howard K. Gray, September 4; The Management of the Simple Skin Diseases, Lieut. Col. Everett R. Seale, September 18.

U. S. Naval Hospital, Santa Margarita Ranch, Oceanside: Cardiac Pain, Lieut. Comdr. Robert L. Langley, September 13; Differentiation Between the Protozoal and the Bacillary Dysenteries, Dr. John F. Kessel, September 27.

U. S. Naval Air Training Station, San Diego: Clinical Aspects of Rheumatic Fever, Lieut. Comdr. George C. Griffith, September 6; Problems in Tuberculosis, Comdr. W. L. Rogers, September 7; The Malingering Tests, Dr. John Mackenzie Brown and Mr. Raymond Brown, September 21.

U. S. Naval Hospital, Long Beach: Problems in Tuberculosis, Comdr. W. L. Rogers, September 19.

U. S. Naval Hospital, Corona: Allergy, Dr. John Lamson, September 13; The Rh Factor, Capt. George Macer, September 27.

ORGANIZATION SECTION

Bureau of Information

SUMMARY SHEETS FROM MONTANA AND NEBRASKA

Completed county summary sheets have been received from most of the counties in Montana and Nebraska through Dr. R. F. Peterson, secretary, Medical Association of Montana, and Dr. R. B. Adams, secretary, Nebraska State Medical Association.

The accompanying table gives data from selected counties in each of these states. The column giving the number of persons per telephone is used as one index of the economic status of the area. Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities. *They are not included in computing physician* population ratio, however, as the future needs of the communities will be largely dependent on younger physicians.

Montana

County [1]	Principal Cities [2]	Population	Physicians Under 65	Persons per Physician	Persons per Telephone [3]
Big Horn		8,494	2	4,247	42
Blaine		7,739	4	1,935	33

1. Bureau of Census, estimated population 1943.
2. Bureau of Census, population 1940.
3. Based on 1940 figures, American Telephone and Telegraph Company.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Council on Medical Service and Public Relations

PREPAID MEDICAL CARE

Medical Service and Indemnity Plans Sponsored by County and State Medical Societies

Consistent increase in membership marks the medical insurance plans sponsored by county and state medical organizations. This is the outstanding conclusion of the preliminary survey of many of these plans which has just been completed by the Council on Medical Service and Public Relations of the American Medical Association. Without exception the number of persons covered by these plans has shown a substantial increase within the last year; for example, Colorado 300 per cent, Wilmington, Del., 250 per cent, Massachusetts 400 per cent, Milwaukee 1,200 per cent, Kansas City 300 per cent, two New York plans 100 per cent. The Toledo, Ohio, plan has jumped from nothing a year ago to 43,273 subscribers now.

A study made by the Bureau of Economics of the American Medical Association in 1937, showing the growth in membership for thirty-five Blue Cross hospitalization plans between January 1936 and 1937, represents an increase in membership of 138 per cent during the twelve months. The number of members increased more than 200 per cent for the ten largest plans. For one plan the increase was 700 per cent. Although these voluntary medical plans have come into nationwide prominence only recently, the study shows that the movement has gained tremendous momentum during the last year and the figures compare favorably with those of the longer established Blue Cross plans of hospital insurance, when compared with the corresponding years of early operation. When the study of group hospitalization plans was made in 1937 the total membership was 700,000, the three largest plans having 49 per cent of all members. At the present time Blue Cross plans cover some twenty million people.

This present preliminary study on medical insurance programs indicates that a growth can be expected for these medical plans within the next eight years similar to that which marked Blue Cross from 1937 to 1945.

The first medical plan is believed to have been started in 1917 in Pierce County in the state of Washington. Little progress was made during the next decade. A rapid increase in number and size of these organizations was made during 1933-1940, when most of the county bureaus in the state of Washington were established. The most rapid growth has come since 1939, when statewide plans were started in Michigan and California.

In addition to plans now in operation, enabling legislation has been passed in several states in anticipation of the establishment of medical service plans. Active studies are now under way in Connecticut, Indiana, Illinois and several other states which should result in the early establishment of additional voluntary prepayment plans under the direction of or with the approval of state medical organizations. According to the information collected, the largest plan now in operation in point of membership is the Michigan Medical Service, which on May 31, 1945 had 777,104 subscribers.

The table on the following pages shows the wide variety of coverage. Also evident is the fact that the legal authority for the creation of the different plans varies greatly from state to state. Additional studies of these plans and other voluntary insurance plans will be made from time to time by the Council and the results published in THE JOURNAL.

Medical Service Plans

LOUIS H. PINK TO REORGANIZE INSURANCE INDUSTRY IN PHILIPPINES

Louis H. Pink, president of Associated Hospital Service of New York and former superintendent of insurance of the state of New York, is en route for Manila, where he will serve temporarily as special adviser to the Philippine government in the reorganization of the insurance industry of the islands, it was announced on June 18 by Jamie Hernandez, secretary of finance of the Philippines. Mr. Pink accepted the Philippine post in response to a personal appeal from President Sergio Osmena.

Leonard M. Gardner of Portland, Ore., who is accompanying Mr. Pink as associate adviser, will remain in the islands for an indefinite period to assist the Philippine government in carrying out the program of reorganization.

The resolution of the board of directors of Associated Hospital Service of New York granting Mr. Pink leave of absence until September to serve the Philippine government is in keeping with the organization's policy of cooperation in public service activities.

INCORPORATORS OF CONNECTICUT MEDICAL SERVICE

Six members of the Connecuticut State Medical Society have been named incorporators of the Connecticut Medical Service, the prepayment plan which is soon to be launched in the state. The society's representatives are Edmund L. Douglass, Groton; Ira V. Hiscock, professor of public health, Yale University School of Medicine; H. Goldersleeve Jarvis, Hartford; James Raglan Miller, Hartford; J. Harold Root, Waterbury, and Charles H. Sprague, Bridgeport. Five laymen active in civic affairs, particularly in the health and welfare field, are the remaining members of the board: Dr. D. Spencer Berger, treasurer, Berger Brothers, New Haven; Wallace E. Campbell, secretary, Fuller Brush Company, Hartford; J. William Hope, president, J. William Hope Company, accountants, Bridgeport; Robert S. Judd, vice president, Southern New England Telephone Company, New Haven; Edward J. Quinlan, judge of the superior court, Norwalk.

WARNER EXPANDS GROUP INSURANCE PROGRAM

A liberal expansion in the group insurance program of William R. Warner & Co., Inc., and its subsidiary companies, Richard Hudnut and Standard Laboratories, Inc., was made effective May 1 according to an announcement by John H. Holzbog, vice president in charge of industrial relations. In addition to the life insurance program which the company had previously carried for its employees, the new plan includes accidental death and dismemberment coverage, weekly sickness and accident benefits, surgical benefits, daily hospital benefits of $5 a day for employees and dependents, and an additional allowance for special hospital charges of five times the daily hospital benefit, which also extends to employees and their dependents. Employees who have been with the company for three months or more are eligible for the full coverage. The plan will include employees of the company's plants in New York, St. Louis and Mamaroneck as well as all salesmen and field representatives in the United States. Approval has also been sought from the Canadian War Labor Board for including employees of the company in Canada. The entire cost of the program is being carried by the company.

The plan is being underwritten by the Travelers Insurance Company of America.

Medical Service Plans—Continued

Annual Expenditure	Surplus and Reserve	Income Ceiling	Annual Benefit Limit	Legal Authority	Date Figures Based	Comment
Less than 1 yr. in operation	$10,000	None	Limited to $250 maximum for each person on agreement	State of Nebraska under assessment insurance law	6/30/45	Organization only in operation 8 months
$9,449.07	$4,331.44	None	None	State law	8/1/44 to 12/31/44	
$2,400,000.00	$75,000.00	None	One year's total service and 6 months hospital service for any single ailment	License from Oregon State Insurance Dept.	5/1/45	No definite income ceiling set but coverage of high income people avoided wherever possible

Medical Economic Abstracts

MEDICAL SERVICE PLANS IN CONTINENTAL COUNTRIES

This is the first of a series of abstracts on medical service plans in foreign countries which will appear in THE JOURNAL from time to time, prepared by the Council on Medical Service and Public Relations. The following was taken from the *British Medical Journal:*

Denmark

Denmark's peculiar contribution to social legislation lies in the field of social insurance. The state organizes and regulates insurance and in part runs the insurance administration itself. National insurance covers the entire population. Previous to what is known as the Social Reform—a mass of social legislation which was passed in 1933—there was a voluntary system of sick clubs or sickness benefit societies which covered about two thirds of the population, and this has been preserved within the national compulsory system. Every person on reaching 21 is required to become a member either of a sick club or of a state-controlled sickness insurance institution. In the sick club there are two classes of members. The "active members" consist of those who are "unpropertied"; that is, with an annual income of less than about 3,500 kroner (just under £200). The second class, the "passive members," consist of those who are above the income level and are not eligible for the benefits of the club, but should their income fall below the stated level they may, irrespective of their state of health, on complying with the conditions become "active members."

In illness the sick club provides its "active members" with entirely or partly free domiciliary medical attendance, free treatment at a hospital (where the municipality meets half the expense), two thirds of the expenditure on medicines and cash benefit up to twenty-six weeks. Special maternity benefits have been introduced.

There are 1,650 sick clubs, all separate units but all subject to state supervision. Of their total income about 68 per cent comes from members' contributions and 28 per cent from state and communal grants. The real significance of the general obligation brought about by the National Insurance Act to be a member either of a sick club or of a national insurance institution lies in the fact that the act also introduced a general and compulsory invalidity insurance the premium for which is collected with the sick club contribution, and also that no one can obtain the old age pension without being a member. Thus the provision of help in sickness, in invalidity and in old age is joined together in a common insurance system.

Under social insurance medical service is provided by practitioners working under agreements. The agreements are divided into two different categories. Outside Copenhagen the insurance institutions have no authority to select practitioners; all physicians who report to the regional section of the Danish Medical Association that they are willing to serve may be placed on the list. In Copenhagen, on the other hand, the doctors are engaged by the insurance institutions. Nearly all medical practitioners in Denmark, except the specialists, engage in insurance practice. Doctors may be remunerated either by a capitation fee or according to a schedule of fees for the services they render. The amount paid for medical services is divided about equally between these two forms of arrangement.

Considerable choice of doctor is allowed to the patient in Copenhagen, though not complete free choice. The city is divided into three main districts, and insured persons may make their choice among the local contracting physicians in their district. However, no physician may accept more than 1,500 persons as potential patients, and consequently this limits free choice.

Washington Letter

(From a Special Correspondent)

Aug. 13, 1945.

Hawley Reported to Be New Medical Chief of Veterans Administration

The new medical director of the Veterans Administration is expected to be Major Gen. Paul Hawley of the Army Medical Corps, who since January 1943 has been chief surgeon of the Army in the European theater. General Bradley, new Veterans Administrator, who worked with General Hawley, is expected to announce the appointment when he takes over as Veterans chief this week. The job was reported to have been lined up previously for Col. Howard A. Rusk of the Army Air Forces, who conferred with President Truman and General Bradley on a rehabilitation program for war veterans General Hawley is a native of Indiana and a graduate of the University of Cincinnati Medical School.

Request for Four State Pollution Survey of the Potomac River

The U. S. Public Health Service has been asked by the newly organized Interstate Commission for the Potomac River Basin to make a pollution survey of the 14,500 square mile drainage area in four states, according to an announcement from Hershey, Pa. The commission, pending receipt of the requested data, has tentatively divided the basin into three water use classification. It recommends treatment of all water taken from the Potomac and its tributaries. The commission includes representatives of Pennsylvania, Maryland, Virginia, West Virginia, the District of Columbia and the federal government. It has classified as unfit for either drinking or swimming the waters of the Potomac in Metropolitan Washington, the Luke-Cumberland area and the north branch to Patterson creek, described as the worst polluted sections of the basin.

UNNRA to Combat Yellow Fever Throughout the World

Dr. Fabio Carmeiro de Mendonca, Brazilian physician and director of quarantine for Brazil, who arrived here from Rio de Janeiro recently, states that "UNNRA will shortly inaugurate a world campaign for the eradication of yellow fever. It will be one of its major projects in disease prevention. The yearly death toll from this disease is considerable. It is quite prevalent in the islands of the Pacific. Brazil is no longer menaced with yellow fever as it is known in the United States. We do have some infectious diseases similar to yellow fever." Dr. Mendonca conferred here with prominent U. S. medical authorities on preventive measures for yellow fever.

Improvement of German Health and Sanitation in United States Zone

Steady improvement in restoration of German health and sanitation, economy and local civil government is reported in the U. S. zone of occupation by the War Department. The report said that health conditions are gradually being bettered. Typhus has decreased. Tuberculosis and venereal disease have been serious among displaced persons. Typhoid, dysentery, diphtheria and scarlet fever cases are being reduced. Food continues to be a primary concern, with Allied displaced persons receiving, through priorities, daily diets of 2,000 calories. Water services have been restored for drinking water at least. Selected industries are making critical items such as soap, fertilizer, insecticide and processed food.

Development of Improved Artificial Hand by Navy Technicians

An improved artificial hand made of plastic materials, which is said to be natural looking and far superior in use and appearance to anything previously devised, is revealed as the work of dentists and enlisted men working under Capt. Rae D. Pitton and Lieut. Comdr. LeMar W. Harris, former Chicago dentist, at the Naval Dental School, Bethesda, Md. Dr. Harris got his start in plastics making artificial teeth. Following research extending over more than a year, they are said to have produced a hand that looks real, doesn't require wearing a glove, is almost as efficient as a hook, picks up and holds articles in a rubber-like grip and weighs less than a pound. While some amputees will get the new hand soon, mass production is not expected for some time. The prosthetic appliance is made of a special plastic and is tinted to match the patient's skin. A 1 pound cam mechanism hidden inside the hand is said to permit natural finger movement. The mechanism is operated by a cord running up the arm and around the shoulders. Control is by the shoulder muscles. The new hand is the first improvement in artificial limbs to be announced since the government's appeal for new ideas.

Standardized Form of Treatment for Poliomyelitis Predicted

Standardization of treatment for infantile paralysis is predicted by District of Columbia medical men. They expect that medical research now under way will combine the best features of the Kenny and other treatments to develop the most effective system. Dr. P. A. McLendon, chairman of the Children's Hospital poliomyelitis committee, reports that types of treatment differ with individual physicians. Some methods are successful in some cases and failures in others. As an illustration, ultraviolet irradiation, drawing out blood and bathing it with violet rays helps to combat infection in bulbar poliomyelitis, but it does not help spinal paralysis cases. The Kenny hot pack and manipulation method was said to have both advantages and disadvantages. While this treatment helps some patients, the extreme heat is believed to be detrimental to the patient's health.

Capital Notes

In a rabies control program, District of Columbia medical authorities have announced that 35,000 dogs will be vaccinated by September 7 at ten strategically located clinics.

District school teachers are studying improved health education methods at daily conferences in Wilson Teachers College. Speakers include Dr. Irma Nevins, national director of accident prevention, Red Cross; Frank S. Stafford, chief of health education, U. S. Office of Education, and Miss Bosse Randle, special consultant, school health services, Children's Bureau.

Russell Green, a University of Maryland sophomore whose left side was paralyzed when he was 10, is demonstrating to disabled veterans in Walter Reed Hospital how he learned to walk, dance, swim, type with one hand and tie his shoes.

Dr. Paul F. Douglask, president of American University, has announced plans for a $2,000,000 six story center of social science and public affairs.

Woman's Auxiliary

West Virginia

Dr. W. W. Bauer, director of Health Education of the American Medical Association, and Dr. Harry V. Thomas, president of the Harrison County Medical Society, were the guest speakers of the Harrison County Auxiliary Doctor's Day Program.

The Raleigh County Woman's Auxiliary recently announced the establishment of a "Book Shelf" at the Pinehill Sanitarium

Mrs. U. G. McClure, president of the Woman's Auxiliary to the West Virginia State Medical Association, recently announced the appointment of a Physicians Advisory Board for 1945-46, as follows: Drs. Hu C. Myers, Philippi; H. V. Thomas, Clarksburg; John P. Helmick, Fairmont; Scott A. Ford, Beckley, and U. G. McClure, Charleston. The following chairmen of standing committees have been appointed by Mrs. McClure to serve with other chairmen named late in May: convention, Mrs. Edwin J. Humphrey, Huntington; press and publicity, Mrs. W. Paul Elkin, Charleston, and speakers' bureau, Mrs. John W. Hash, Charleston.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTERFST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Faculty Changes.—Frederick E. Emery, Ph.D., associate professor of physiology, University of Buffalo School of Medicine, Buffalo, N. Y., has been appointed professor of physiology and head of the department of physiology and pharmacology of the University of Arkansas School of Medicine, Little Rock. John E. Davis, Ph.D., is professor of pharmacology in the department.

State Cancer Commission Created.—Under recent action of the legislature, a state cancer commission has been created to coordinate and direct a cancer control program in Arkansas to be financed by an initial appropriation of $25,000. The law providing for the commission stipulates that the funds may be used to furnish medical, hospital and home care for indigent cancer patients and may be matched with county and city funds in making available care for persons not wholly indigent. According to the *Field Army News* of the American Cancer Society, the commission may accept voluntary contributions and disburse any federal funds available for cancer control, conduct clinics wherever necessary in the state and institute educational programs in cooperation with established organizations as well as utilize facilities of private physicians and hospitals and the University of Arkansas School of Medicine. Gov. Ben Laney has been named chairman of the Arkansas State Cancer Commission and Dr. Carl A. Rosenbaum, associate professor of surgery at the medical school, secretary.

COLORADO

Anniversary Year of State Medical Society.—The Colorado State Medical Society this year will observe its seventy-fifth anniversary. Plans are under way to mark the occasion in some special manner.

New Professor of Pathology.—Dr. James Bernard McNaught, associate professor of pathology, Stanford University School of Medicine, San Francisco, has been appointed professor of pathology at the University of Colorado School of Medicine, Denver. Dr. McNaught graduated at Stanford in 1931.

Building Fund Revived.—On June 26 twenty past presidents of the Medical Society of the City and County of Denver gave a dinner to the members of the society to mark the revival of the dormant building fund campaign. Talks at the dinner revealed the status of homes owned by other societies and the facilities of other libraries as compared with the library facilities of the Denver society. A site has not been selected for the proposed permanent home of the society, the choice to be deferred until a majority of all members has voted its choice of location.

CONNECTICUT

Clinical Congress Canceled.—For the first time in twenty-six years the clinical congress of the Connecticut State Medical Society will not be held this fall.

Personal.—On June 1 Mr. Berger E. Foss, superintendent of the Knickerbocker Hospital, New York, became director of Newington Home for Crippled Children, a 200 bed orthopedic children's hospital, Newington, succeeding Miss Constance Leigh, R.N., who retired after twenty-seven years' service in that capacity.

ILLINOIS

Governor Vetoes Medical Bill.—The Allison bill, which was passed by the legislature and which would have made it unlawful for any physician or surgeon to refuse emergency or first aid treatment to an accident victim, was vetoed July 24 by Governor Green, according to the Chicago *Sun*.

Maude Etheredge Resigns at Illinois.—Dr. Maude Lee Etheredge, director of the women's health service and professor of hygiene, University of Illinois, Urbana, has resigned after twenty-two years' service to the university, according to the Urbana *Courier*, July 2. The resignation will be effective September 1. Dr. Etheredge graduated at Bennett College of Eclectic Medicine and Surgery, Chicago, in 1911. Prior to joining Illinois in 1923 she acted as medical adviser and was director of the women's health service at Cornell University, Ithaca, N. Y.

Chicago

Course in Bronchoesophagology.—The department of otolaryngology, University of Illinois College of Medicine, will offer a special course in bronchoesophagology, October 15-27, under the personal direction of Dr. Paul Holinger, assistant professor of laryngology, rhinology and otology. The course will consist of didactic lectures, animal and cadaver demonstrations, practice in bronchoscopy and esophagoscopy, diagnostic and surgical clinics and other work. Registration will be closed when the limited number of twelve applications of physicians have been received. Additional information may be obtained from the Department of Otolaryngology, University of Illinois College of Medicine, 1853 West Polk Street, Chicago 12.

Emotional Adjustments of Civilians and Veterans.—The Illinois Society for Mental Hygiene is offering its services in the planning of educational programs to promote better understanding of the emotional adjustments of civilians and veterans. The service is available, without charge, to organizations wishing a list of speakers, a series of appropriate movies and a selection of literature for distribution or sale. Arrangements for hall, speakers, movies and audience will be left to the organization wishing the planning service. If the group wishes the Illinois Society for Mental Hygiene to conduct programs, a charge will be made for the cost price of the speakers' fees, movies and any other expense incurred. Additional information may be obtained from the Illinois Society for Mental Hygiene, 343 South Dearborn Street, Chicago 4.

KANSAS

Postgraduate Fund.—The Kansas Medical Society has voted to raise a fund of $100,000 to assist returning medical officers in obtaining postgraduate medical education before reentering private practice. A questionnaire has been sent to each member of the society now serving with the armed forces asking his plans for postgraduate education. Dr. William P. Callahan, president of the Kansas Medical Society, has appointed as a committee to study the distribution to be made of the fund of $100,000, more than $36,000 of which is now available, Drs. Harold H. Jones, Winfield, chairman; Floyd C. Beelman, Topeka; Clarence H. Benage, Pittsburg; Louis B. Gloyne, Kansas City; John L. Lattimore, Topeka; Benjamin H. Mayer, Ellsworth, and James H. A. Peck, St. Francis. It has already been decided that each medical officer desiring postgraduate medical education shall have the opportunity of receiving assistance from the fund and that each shall select the school and the course of study he prefers. The *Journal of the Kansas Medical Society* states that contributions to the fund are voluntary but that it is hoped each member will send in a donation.

KENTUCKY

Hugh Leavell Joins Rockefeller Foundation.—Dr. Hugh R. Leavell, Louisville, director of the Jefferson County Board of Health, who has been on leave with the UNRRA in Europe, has been appointed an assistant director for the medical sciences for the Rockefeller Foundation. The appointment will be effective in the fall, when his association with the UNRRA ends. Dr. Leavell has been connected with the Jefferson board of health since 1934.

MISSOURI

Personal.—Dr. Curtis H. Lohr, St. Louis, was to resume his activities June 15 as superintendent of the St. Louis County Hospital, Clayton, after a two year absence on overseas duty with the army.——Dr. William E. Angell, Rocheport, recently observed the fiftieth year in the practice of medicine.

The Doctor Prefix Bill.—House Bill 206, known as the "Doctor Prefix Bill," has been approved by the governor and will become law ninety days after the adjournment of the present session of the legislature, which is not expected until after January 1. To comply with the law, physicians should change their office name plates, cards, stationery, signs and so on by adding M.D. after the name whenever the word "Doctor" or "Dr." is used before the name. The law applies as well to dentists, osteopaths, veterinarians, chiropractors, chiropodists or any other persons who profess to be practicing the healing art and who use the prefix "Doctor" or "Dr."

Study of Tuberculous Pulmonary Calcification in Children.—The U. S. Public Health Service has established a laboratory at the University of Kansas School of Medicine, Kansas City, with a mycologist in charge to carry on a study of tuberculous pulmonary calcification. In cooperation of the local health department and the Kansas City Tuberculosis Society, the public health service is conducting a field study among the children, consisting of a tuberculosis and histoplasma skin test with an x-ray plate of the chest. The U. S. Public Health Service in 1944 investigated the question of pulmonary calcification in the absence of the tuberculin positive skin test, carrying on investigations in Detroit, Minneapolis, Philadelphia and Kansas City. Histoplasmin skin tests were made concurrently with tuberculin tests, and results suggest that much of the pulmonary calcification hitherto suspected of being tuberculosis is in reality due to a subclinical infection with Histoplasma capsulatum or an immunologically related organism.

NEBRASKA

Personal.—Dr. Charles W. Rudolph, Houston, Texas, has been appointed in charge of the Hospital for the Tuberculous, Kearney, succeeding Dr. Leland C. Albertson, resigned (THE JOURNAL, May 19, p. 216).

Hospital News.—Ground for the proposed 50 bed $270,000 Provident Hospital, Omaha, to be built by the Nebraska Negro Medical Society and other sponsoring groups, was bought July 9. The site is at Thirtieth and Wirt streets.

First Fellowship Under Poynter Foundation.—Philip D. McIntosh, B.S., who has completed his first two years of medicine in the University of Nebraska College of Medicine, Omaha, has been selected as the first C. W. M. Poynter Foundation Fellow in medical science for a period of a year beginning July 1 (THE JOURNAL, March 3, p. 534).

NEW JERSEY

"Polio" Quarantine in Trenton.—On August 5 a poliomyelitis quarantine became effective in Trenton, barring children under 16 years of age from churches, Sunday schools, theaters, stores, playgrounds, parks and gatherings of any kind. A resolution imposing the quarantine and fixing penalties for parents or others permitting violations by children was adopted by the city commission on August 4. Two days previously Dr. William E. Mountford, city health officer, asked the commission to act, and when it failed to do so he asked the public to comply voluntarily with his proposal. According to the New York *Times*, the number of poliomyelitis cases on August 4 totaled 45, with eight deaths.

NEW YORK

Memorial Library to Honor Physician.—Members of the medical staff of the Mount Vernon Hospital, Mount Vernon, and of the Mount Vernon Medical Society, as well as personal friends, are cooperating in the establishment of a library at the Mount Vernon Hospital to be named the Dr. Ludwig B. Goldhorn Memorial Library. The library will honor Dr. Goldhorn, who died Nov. 16, 1944 after serving the hospital for thirty-six years as roentgenologist, during which he established the first x-ray laboratories there.

Cancer Teaching Day.—On October 17 a cancer teaching day will be held at the Governor Clinton Hotel, Kingston, under the auspices of the Medical Society of the County of Ulster, the Third District Branch of the state medical society, the Tumor Clinic Association of the State of New York, the medical society and the state department of health's division of cancer control. Speakers will include:

Dr. Earl D. Osborne, Buffalo, Cancer of the Skin and Allied Tumors.
Dr. Frederick S. Wetherell, Syracuse, Role of the Practicing Physician in the Care of Cancer.
Dr. Charles B. Huggins, Chicago, Cancer of the Prostate.
Dr. Fred W. Stewart, New York, Biopsy in Tumors.

Agencies Named for Hospital Survey.—To make the proposed new hospitals in the state eligible for federal funds under the pending Hill-Burton hospital construction bill, Governor Dewey on August 2 designated the Postwar Planning Commission as the single state agency for surveys as required in section 612 (a) (1) of the bill and set up a Joint Hospital Board composed of the commissioners of health, mental hygiene and social welfare to coordinate activities in these fields which are required in the survey. The Joint Hospital Board will act for and with the planning commission in making the necessary inventory and survey of hospitals in the state. Needed experts are to be employed with funds furnished by the Postwar Planning Commission. The state advisory council required in section 612 (a) (2) of the Hill-Burton bill will be designated by the Joint Hospital Board.

New York City

Course in Hospital Administration.—Columbia University announces that, aided by a grant from the W. K. Kellogg Foundation, it will offer a course in hospital administration beginning September 27. The course will be of approximately twenty-one months' duration, consisting of an academic year in residence and a calendar year of supervised assistantship in an affiliated hospital. A baccalaureate degree will be a minimum requirement. Women will be admitted on the same terms as men. The course will be offered through the School of Public Health of the faculty of medicine of the university, according to an announcement.

Changes at Columbia.—Drs. James Wesley Jobling and Alwin Max Pappenheimer, professors of pathology at Columbia University College of Physicians and Surgeons, have been designated professors emeritus, the New York *Times* of July 26 reports. Dr. Jobling, who graduated at Lincoln Memorial University Medical Department, Knoxville, Tenn., in 1896, has been associated with Columbia since 1918. Dr. Pappenheimer, who graduated at Columbia in 1902, has been associated there since 1909. Aura E. Severinghaus, Ph.D., and Dr. Vernon W. Lippard are associate deans for medicine at Columbia. Dr. Harry S. Mustard, director of the DeLamar Institute of Public Health, is associate dean for public health.

Progress of Plans for Tropical Disease Hospital.—On July 16 federal approval was given to an advance of $76,000 to the city of New York to help finance the preparation of plans of a $2,200,000 hospital for tropical and communicable diseases to be constructed after the war. The federal advance, made through the bureau of community facilities, FWA, will be supplemented by $19,000 authorized by the board of estimate. The hospital will have a capacity of 300 patients. It is to be built on a tract facing the Hudson River, between 165th and 168th streets, and transferred to the city by agreement with Columbia University and the Presbyterian Hospital of the City of New York. On the same tract, a short distance north of the hospital, the city proposes to build a $2,690,000 public health laboratory, research and training center (THE JOURNAL, June 9, p. 453).

WASHINGTON

New Rule Relating to Medical Treatment.—The state department of labor and industries has reported to the Washington State Medical Association the adoption of a new rule relating to medical treatment, effective June 7. The rule stipulates that in any case in which the original report and diagnosis of the attending physician is used as a basis for the rejection of the claim, the physician shall be entitled to payment for his services on the first call, including x-rays and laboratory work necessitated for diagnostic purposes, in accordance with the fees prescribed in the fee schedule. In the past, when the department found it necessary to reject a claim on the basis that the condition present was not the result of an injury, and that action was based on the report of the attending physician, the physician's bill was also rejected. In other words, he was penalized for reporting the exact facts. The new rule will overcome that situation.

WEST VIRGINIA

Physicians Urge Extension of Current Medical Care.—The expansion of existing nonprofit medical and hospital service plans and the development of new plans to make medical and hospital care available to people residing in every part of West Virginia was recommended to the legislative interim committee by eight medical members of the recently appointed advisory committee (THE JOURNAL, June 23, p. 606). The plan was recommended in preference to a statewide plan. At the present time there are ten hospital service plans and nine medical service plans in operation in this state. The committee recommended that service corporations be developed and operated separately and that hospital care be made the responsibility of participating hospitals and medical service the responsibility of participating physicians. In the interest of economy of operation, the committee feels that hospital service groups should be permitted to serve as public agents for medical service corporations in the same area. The committee also recommended that reciprocal relations be arranged by which a member of a service group in one area may receive hospital or medical service in any other area of the state where service plans are in operation. It is felt that service outside the state should be on an indemnity basis only, unless reciprocal arrangements can be made by the plans operating in West Virginia and those in operation in other states. Under the plan recom-

mended by the doctor group, all state employees would be eligible to participate on a voluntary basis in nonprofit medical and hospital service plans, with provisions for salary deductions at the source covering this service. The group unanimously recommended that a division of medical and hospital service be created in the state health department under the supervision of a director, who would have such regulatory powers over nonprofit service plans as may hereafter be defined. The director would have the assistance of an advisory committee appointed by the governor, composed of two representatives each from the West Virginia State Medical Association, the Hospital Association of West Virginia, nonprofit hospital service plans operating in West Virginia and the public. The committee urged that at least one third of the members of the directing board of the various nonprofit hospital and medical service plans should be representatives of the public at large; that is, persons who are not doctors and who have no hospital affiliations. The group declared that the funds provided at the present time for medical and hospital care for the indigent have proved to be wholly inadequate for the purpose and recommended that a substantial increase be made in the appropriation. The revised plan would provide for emergency hospital and medical service for the indigent on a twenty-four hour basis. Dr. Robert J. Wilkinson, Huntington, chairman of the medical members of the advisory committee, submitted the report for the group. He stated that the program as outlined is acceptable to all of the service plans now in operation in the state with the exception of the recommendation for supervisory and regulatory control by the director of a new division to be created in the state health department. Six of the service plans favor regulation by the insurance commissioner, while representatives of two of the plans favor the creation of a new division.

GENERAL

Ophthalmology Examination Postponed.—The American Board of Ophthalmology announces that because of transportation difficulties the examination of the board, originally scheduled for Chicago in October, has been postponed to Jan. 18-22, 1946. Examinations of the board will be Chicago January 18-22, Los Angeles January 28-February 1, New York in May or June and Chicago in October.

Antinoise Awards.—Memphis, Tenn., was named first prize winner of the Grand National award, a gold plaque, presented for the first time this year by the National Noise Abatement Council, New York. Winners of the 1945 four city population group awards, silver plaques, include group I (cities over 500,000), Chicago; group II (250,000 to 500,000), Rochester, N. Y.; group III (100,000 to 250,000), Salt Lake City, Utah; group IV (less than 100,000), Little Rock, Ark.

Publicity Program for Radiology.—The commission on public relations of the American College of Radiology has received a grant of $15,000 from the National Electrical Manufacturers' Association to conduct a publicity campaign in connection with the commemoration of the fiftieth anniversary of Roentgen's discovery of the x-rays. The campaign will be directed by a joint committee representing the college and the manufacturers' association. Through newspapers, periodicals and the radio, the role of the specialist in radiology as a doctor and consultant will be described. The campaign will end November 8, the fiftieth anniversary of Roentgen's discovery.

Ammonia.—The rapid growth of new chemicals and the widening industrial use of well known ones, especially during the war, has led the Division of Labor Standards in the U. S. Department of Labor to inaugurate a series of bulletins on controlling chemical hazards in cooperation with the Manufacturing Chemists Association of the United States, according to V. A. Zimmer, director. The first bulletin, "Ammonia," is just off the press and others shortly to be issued cover chlorine, sulfuric and nitric acids, formaldehyde and the anilines. There will be over a hundred such bulletins in the series. These bulletins are designed for safety men in industry, insurance companies and state labor departments, for union safety committees and for materials warehousemen, handlers on railroads and trucking concerns, industrial doctors and nurses and firemen and fire prevention authorities. Each bulletin describes the hazards of the chemical, its characteristics, safety precautions for installation, handling and storage, protective clothing, permissible and hazardous concentrations, and first aid treatment. A bibliography is included. Each bulletin is checked for technical accuracy and practical safeguards with firms manufacturing the chemical through the Manufacturing Chemists Association. "Ammonia" will be of special interest to refrigeration and air conditioning manufacturers, oil refineries, steel treatment and water purification plants, manufacturers of sulfuric and nitric acids, fertilizer, drugs and chemicals, and bottling works. A supply of up to twenty-five copies will be distributed without charge on request by the Division of Labor Standards as long as the free supply lasts. Larger orders may be obtained for 5 cents a copy from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A 25 per cent discount is allowed on orders of 100 or more.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended August 4 have been received from the division of public health methods, U. S. Public Health Service, as follows:

Four Million Dollars for Cancer Research.—The Alfred P. Sloan Foundation has given $4,000,000 to provide and in part to maintain a proposed Sloan-Kettering Institute for Cancer Research, to be organized in conjunction with Memorial Hospital for Cancer and Allied Diseases, New York. The gift will provide for a building especially designed for the purpose and self contained in all its various research functions. It will be erected at an estimated cost of $2,000,000 on property now owned by Memorial Hospital adjacent to its present location. The facilities to be provided will be adequate to permit the exploration of all avenues that may be expected to contribute to the objective. The entire project will be in keeping with a program of expansion at Memorial Hospital. In addition, the Alfred P. Sloan Foundation will undertake to provide $200,000 a year toward the operating cost for a definite period of ten years. In a statement to the press, Reginald G. Coombe, president of the hospital, said that, while the Alfred P. Sloan Foundation gift provides for most of the financial requirements of the research phase of the proposed Memorial Cancer Center, the center will not be fully effective from the point of view of its ability to render service until it is completed. It is planned to launch a public campaign to obtain the necessary $3,000,000 to $4,000,000 to provide for an increased bed capacity at Memorial Hospital proper, for fellowships for the training of specialized medical personnel and for equipment necessary to the servicing of the new Dr. James Ewing Hospital for Cancer to be erected at the center by the city of New York. The new institute will bear the name of the two men who have cooperated in many scientific endeavors, Alfred P. Sloan Jr. and Charles F. Kettering, chairman and vice president and director of research, respectively, of General Motors. Mr. Sloan created the Alfred P. Sloan Foundation to advance in any proper way the interest of the community at large, with emphasis on economic education, giving to it in 1937 an endowment of $10,000,000 to provide for expanded activities.

Deaths in Other Countries

Dr. Henry R. Kenwood, emeritus professor of hygiene and public health, University of London, died June 7, aged 82. —**Dr. Edward Barclay-Smith**, emeritus professor of anatomy, University of London, died in London, aged 84.— **Dr. Philippe Dally**, noted physician and Paris correspondent of THE JOURNAL, died in Paris July 5, aged 75.

The New Chair of Human and Comparative Anatomy at the Royal College of Surgeons

Thanks to the munificence of Sir William H. Collins, a new chair of human and comparative anatomy has been founded at the Royal College of Surgeons. The first to hold it is the distinguished anatomist F. Wood Jones, who occupies the chair of anatomy at the University of Manchester. After graduating in the University of London in 1904 he became demonstrator of anatomy at the London Hospital and St. Thomas's Hospital. After some years as medical officer in the Far East he was appointed anthropologist to the Egyptian government and took part in the archeological survey of Nubia. In 1919 he was appointed professor of anatomy at Adelaide University, which position he resigned in 1927 on taking the Rockefeller chair of physical anthropology in the University of Hawaii. In 1930 he left Hawaii to become professor of anatomy in Melbourne University. In 1932-1933 he acted as director of anatomy in Peiping Union Medical College. He is the author of several books marked by original thinking on corals, arboreal man, the mammals of South Australia, and sea birds as well as "The Principles of Anatomy as Seen in the Hand," "Unscientific Excursions," "Life and Living" and "Design and Purpose."

Inter-Allied Cooperation at the Royal Society of Medicine

This war has to its credit one important benefit—increased contacts between the leaders of the allied countries. In Britain we have been privileged to welcome them in large numbers—from the United States as members of the huge American army quartered here and from the European continent as refugees from German oppression. For the time being they have been honorary members of our medical societies, and the pleasant and profitable contacts with them will be long cherished in our memories. The Royal Society of Medicine, with its membership of over 7,000, has played the leading part in these contacts, of which farewell celebrations have just taken place. At an annual meeting of the fellows the president, Surg. Rear Admiral Gordon-Taylor, presented scrolls of honorary fellowship to certain distinguished persons in medical services of the British and Allied forces. In doing so he addressed the Czech, Norwegian and Belgian recipients in their native languages. The first award was made to Gen. Frantisek Langer, director general of the medical service of the Czech army. The next was made to Dr. Karl Evang, director general of the Norwegian public health services. In returning thanks Dr. Evang said that before the war Norwegian medical science looked to the south, to Germany and Austria, though it had partly turned to Britain and the United States. There would now be a radical change, and more Norwegian doctors would knock at the British door. The last of the allied recipients was Colonel Gallemaerts, director general of medical services of the Belgian army. General Smirnov, head of the medical service of the Russian army, was not able to attend for his presentation. The guests included Brig. Gen. Elliott Cutler of the United States Army in Europe and Col. A. T. Jurasz, dean of the Polish Medical School in Edinburgh. A farewell dinner was also given to the representatives of the Allied forces in this country. The chairman, Sir Henry Tidy, recalled that among the useful subjects discussed by them at the meeting of the society were lifeboats at sea, the psychology of the Germans, army rations, field surgical units, operational strain, psychosis and combat exhaustion, malaria, head injuries, plastic surgery, the prisoner of war, famine in Bengal, typhus, blood transfusion, infective hepatitis, concentration camps and starvation.

BRAZIL

São Paulo, May 26, 1945.

Penicillin in Syphilitic and Parasyphilitic Diseases

Six patients with tertiary yaws were treated with penicillin in small doses at the Evandro Chagas Hospital of the Oswaldo Cruz Instituto in Rio de Janeiro by Dr. F. Nery Guimarães. The lesions presented by the patients were gummatous ulcerations, periostitis, osteitis, osteoporosis and gangoza (rhinopharyngitis mutilans). In all cases clinical recovery was obtained, the time of treatment varying from two to seven months. The number of Oxford units per patient varied from 48,000 to 558,800. Patients with bone lesions, even after treatment, did not show complete repair of the bone structure, but the lesions appeared to be healed and negative serologic tests were obtained.

Dr. Nery Guimarães and his co-workers Drs. Area Leão and Genard Nobrega published their therapeutic researches on syphilitic infection.

Six syphilitic patients were treated with penicillin in small doses at the Evandro Chagas Hospital of the Oswaldo Cruz Institute. Primary lesions were found to be bacterioscopically negative in three to six days, and cicatrized completely in ten to thirteen days with applications of 1,200 to 2,400 Oxford units each in twenty-four hours. Syphilitic condylomas and hypertrophic mucous patches showed negative bacterioscopic results in ten to twenty days with applications of 1,200 Oxford units in twenty-four hours. Doses of 4,800 units during the same time, however, were insufficient to control other secondary syphilitic manifestations (roseolar rash). In 3 cases under serologic control it was found that after a clinical cure had been effected the Wassermann reaction showed considerable oscillation, becoming first negative and then positive.

Brief Items

A postgraduate course in psychiatry and mental hygiene has been inaugurated this month at the Institute of Psychiatry of the University of Rio de Janeiro, under the direction of Prof. Henrique Roxo. Besides Dr. Roxo, Drs. Flavio de Souza, Morais Coutinho, Rodrigo Ulysses and Paulo Lacaz are in charge of the course.

The faculty of the Medical School of the University of Rio de Janeiro conferred the degree of doctor honoris causa on Dr. Pasteur Valéry-Radot, head of the French Cultural Mission to South America, now at Rio de Janeiro.

Marriages

Garrett Michael Swain, Chevy Chase, Md., to Dr. Shirley Catherine Towey of Roselle Park, N. J., in Washington, D. C., May 31.

Thomas A. Keenan, Rutland, Vt, to Miss Christine Elizabeth Kelley of Dorset in New York, April 14.

Norman Blaine Hasler, Worthington, Ind., to Miss Catherine M. McDonald of Orange, Mass., June 14.

William Hugh Hamilton Jr., Hemingway, S. C, to Miss Nanette Sherard of Abbeville, June 23.

Henry Patrick Drake Jr., Marion, Ohio, to Miss Anna Mae Blake of Toledo, June 30.

Arthur Clayton Curtis, Little Rock, Ark., to Miss Grace Roberts of Pine Bluff, June 17.

Robert R. Hays, Akron, Ohio, to Miss Thelma Louise Eppley of Zanesville, May 12.

Jerry Byron Hogsette, Vienna, Ga., to Miss Linda Davis of Sylvania, June 20.

H. W. Davis to Miss Ruth Keene, both of Alton, Ill., June 16.

David Kleiner to Miss Rita Steig, both of Brooklyn, June 30.

Deaths

Egil Thorbjorn Olsen, Detroit; George Washington University School of Medicine, Washington, D. C., 1904; for three years with the U. S. Public Health Service; served as chairman of the program committee of the Wayne County Medical Society, as chairman of the legislative committee of the American Hospital Association and as president of the Michigan Hospital Association; superintendent of the Receiving Hospital from 1929 to 1934; later appointed medical director and assistant superintendent of the Oklahoma University Hospital, Oklahoma City; for many years superintendent of the Englewood Hospital, Chicago; at one time chief medical examiner of the Chicago Civil Service Commission and chief of the bureau of hospitals of the Chicago Health Department; awarded the citation of the Order of Honor and Merit of the Red Cross of Cuba in recognition of services performed in behalf of Cuban residents of Detroit; associated with the medical department of the Ford Motor Company; died in the Henry Ford Hospital June 3, aged 70, of arteriosclerotic heart disease.

James Paul Johnston ⊕ East Moline, Ill.; University of Illinois College of Medicine, Chicago, 1922; formerly health officer of East Moline; a member of the Student Army Training Corps at Iowa University during World War I; commissioned a first lieutenant in the Officers Reserve Corps in 1924; began active duty as a first lieutenant in the medical corps, Army of the United States, on Aug. 14, 1942; served at Camp Breckenridge, Ky., the Army Medical Center in Washington, D. C., and the Billings General Hospital in Indianapolis; relieved from active duty as a captain on Nov. 10, 1943; member of the Iowa and Illinois Central District Medical Association and the Association of American Physicians and Surgeons; on the staffs of the Moline Public Hospital, Moline, and St. Anthony's Hospital in Rock Island; taught obstetrics for four years at the Lutheran Hospital in Moline, serving as the 1945 staff president; died in the Veterans Administration Facility, Hines, Ill., June 10, aged 51, of cerebral thrombosis.

Lewis Henry Koplik ⊕ New York; Western Reserve University School of Medicine, Cleveland, 1928; diplomate of the National Board of Medical Examiners; member of the New York Academy of Medicine, the Harvard Club of New York, the New York Pathological Society, the American Association of Pathologists and Bacteriologists and the Biological Photographic Association and the New York Pediatric Club; instructor in pediatrics at Cornell University Medical College; assistant health officer at the Kips Bay Yorkville Health Center in New York; interned at the Children's Hospital in Boston and was an instructor in pathology at Harvard Medical School; at the time of his death attending physician and member of the board of the Willard Parker Hospital, where he had been an intern, resident and later visiting physician; died at his summer home at Miller Place, L. I., July 22, aged 41, following an operation for the removal of a pituitary tumor.

Harold Denman Meeker ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1902; formerly professor of surgery at the New York Polyclinic Medical School and Hospital; fellow of the American College of Surgeons; consulting surgeon, New York Polyclinic Hospital; member of the medical board of the Doctors Hospital and a consultant to the Somerset Hospital, Somerville, N. J., Yonkers General Hospital, Yonkers, Broad Street, St. Clare's and Downtown hospitals; in 1927 appointed surgical director to the Reconstruction Hospital and in 1935 honorary surgeon in the police department; awarded an honorary degree of master of science from Wesleyan University; died May 26, aged 69, of cerebral hemorrhage.

Benjamin A. Shepard ⊕ Kalamazoo, Mich.; Detroit College of Medicine, 1904; past president of the Michigan Trudeau Society and the Michigan State Tuberculosis Society; past president and secretary of the Kalamazoo Academy of Medicine; past and honorary president of the Kalamazoo Tuberculosis Association; member of the board of directors of the National Tuberculosis Association; fellow of the American College of Physicians and the American College of Chest Physicians; served as medical director of the Pine Crest Sanatorium, Oshtemo; died June 16, aged 65, of coronary occlusion.

Sylvanus F. Basinger, Elyria, Ohio; Cleveland Homeopathic Medical College, 1906; member of the American Medical Association; acting city health commissioner; on the staff of the Elyria Hospital, where he died June 9, aged 67, of chronic myocarditis and pulmonary edema.

Joseph F. Battaglia ⊕ Buffalo; University of Buffalo School of Medicine, 1920; school physician for the city health department; on the staffs of Buffalo Hospital of the Sisters of Charity and the Louise de Marillac Maternity Hospital; died June 3, aged 49, of coronary occlusion.

Abraham Louis Blecker ⊕ Memphis, Tenn.; Memphis Hospital Medical College, 1912; on the staffs of the Methodist and Baptist hospitals; associated with and in 1929 president of the staff of St. Joseph's Hospital, where he died June 13, aged 58, of uremia.

Fred George Bushold, Lawrence, Mass.; Tufts College Medical School, Boston, 1904; died in the Bessie Burke Memorial Hospital June 8, aged 64, of cerebral hemorrhage.

Charles Willard Cole, Norton, Kan.; Central Medical College of St. Joseph, Mo., 1903; member of the American Medical Association; died May 20, aged 67, of coronary occlusion.

Walter Frank Coleman, Hickory Flat, Miss.; University of Tennessee College of Medicine, Memphis, 1915; member of the American Medical Association; also a druggist; served on the board of aldermen; died June 11, aged 60, of carcinoma.

Rufus George Collins ⊕ Chicago; Chicago Medical College, 1885; once on the staffs of the Mercy Hospital and the Michael Reese Hospital, where he died June 24, aged 86, of bronchopneumonia.

George Herbert Davis, East Rochester, N. Y.; University of Vermont College of Medicine, Burlington, 1884; died in the Genesee Hospital, Rochester, April 16, aged 82, of heart disease.

Terence Thomas Dawson, Seattle; Creighton University School of Medicine, Omaha, 1928; member of the American Medical Association; interned at Creighton Memorial St. Joseph's Hospital in Omaha; died May 1, aged 42, of cerebral hemorrhage.

Louis Alfred Dessen ⊕ Hazleton, Pa.; Medico-Chirurgical College of Philadelphia, 1911; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc., and the American College of Radiology; veteran of the Spanish-American War; consultant radiologist, Hazleton State Hospital; died July 10, aged 65, following an operation for carcinoma of the colon.

John Lydall Dixon, Woodbury, Ga.; Atlanta Medical College, 1895; member of the American Medical Association; died in North East, Pa., May 20, aged 69, of pneumonia.

Warren M. Dodge, Farmington, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1893; died in the Miller Hospital, St. Paul, April 28, aged 78, of carcinoma of the sigmoid.

Edward Sylvester Donnelly, Woodburn, Ore.; John A. Creighton Medical College, Omaha, 1912; died in St. Vincent's Hospital, Portland, May 25, aged 60, of heart disease.

Herschell V. Donovan, Cerro Gordo, Ill.; St. Louis College of Physicians and Surgeons, 1895; died in Chicago June 2, aged 72, of arteriosclerotic heart disease.

Arthur Wheeler Drew ⊕ Lieutenant Colonel, U. S. Army, retired, Encinitas, Calif.; Northwestern University Medical School, Chicago, 1913; Medical Field Service School in 1921 and the Army Medical School in 1922; served during World War I; entered the medical corps of the U. S. Army as a first lieutenant on July 1, 1920; retired with the rank of lieutenant colonel on Aug. 31, 1938, for disability in line of duty; died in the U. S. Naval Hospital, San Diego, July 23, 1944, aged 64, of coronary heart disease.

Homan Valentine Duggan ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1893; on the staffs of the Williamsburgh and Wyckoff Heights hospitals; died April 29, aged 73, of coronary disease.

William Lewis Faul, Russellville, Ohio; Cincinnati College of Medicine and Surgery, 1900; member of the American Medical Association; served as county auditor and as county health commissioner; died May 30, aged 70, of carcinoma.

John Grant Foley, Pineville, Ky.; Hospital College of Medicine, Louisville, 1890; member of the American Medical Association; also a dentist; on the staff of the Pineville Community Hospital; died June 12, aged 81, of heart disease.

Robert Sabin Forbes ⊕ Duluth, Minn.; University of Pennsylvania School of Medicine, Philadelphia, 1910; fellow of the American College of Surgeons; served during World War I; on the staffs of the Miller, St. Luke's and St. Mary's hospitals; died April 9, aged 58, of cirrhosis of the liver.

Chester Erwin Fulton, Springfield, Mo.; State University of Iowa College of Medicine, Iowa City, 1888; member of the American Medical Association; instrumental in organizing and

erecting the old Springfield Hospital, where he served as surgeon; died May 22, aged 84, of heart disease and uremia.

Jesse Funderburg, Piqua, Ohio; Columbus Medical College, 1886; formerly county coroner; served on the staff of the Piqua Memorial Hospital; died April 14, aged 82, of cerebral hemorrhage.

Robert Wilson Getty, Deer Lodge, Mont.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; member of the American Medical Association; resident on the staff of the Montana State Tuberculosis Sanitarium; served as coroner and deputy health officer of Valley County; died on the train at Gold Creek April 8, aged 77, of coronary heart disease.

Vincent John Grauten ⊕ Pittsburgh; University of Pennsylvania School of Medicine, Philadelphia, 1917; served during World War I; on the staff of the Presbyterian Hospital, where he died June 7, aged 55, of carcinoma of the prostate.

Richard Alexander Hale, Houston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1919; member of the American Medical Association; part owner of the Park View Hospital, where he died May 20, aged 52, of coronary thrombosis.

John Goold Harvey, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; served during World War I; fellow of the American College of Physicians; died in the Veterans Administration Facility, Dearborn, May 24, aged 69, of Buerger's disease and cerebral hemorrhage.

Friedrich Alexander Hecker ⊕ Ottumwa, Iowa; University of Kansas School of Medicine, Kansas City, 1913; also a dentist; specialist certified by the American Board of Internal Medicine; member of the Society of American Bacteriologists and the American Society of Clinical Pathologists; fellow of the American College of Physicians; pathologist, St. Joseph Hospital, where he died suddenly June 3, aged 66, of coronary thrombosis.

John Blakeslee Henry ⊕ Lawrence, Kan.; University Medical College of Kansas City, Mo., 1903; on the staff of the Lawrence Memorial Hospital, where he died May 8, aged 67, of cerebral hemorrhage.

Thomas James Henry, Apollo, Pa.; Medical Department of the University of Wooster, Cleveland, 1884; member of the American Medical Association; served as vice president of the First National Bank of Apollo; died May 30, aged 86, of cerebral hemorrhage.

Freeman St. Clair Hitchcock ⊕ Greenwich, Conn.; New York Homeopathic Medical College, New York, 1907; associated with the Crest View Sanitarium; served on the board of the Neurological Institute in New York; died in the Greenwich Hospital June 7, aged 62, of heart disease.

William Frank Hunt, Davenport, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1896; died in the Mercy Hospital May 26, aged 74, of prolonged fever and influenza.

Milton T. Jay, Portland, Ind.; Medical College of Ohio, Cincinnati, 1890; past president of the Jay County Medical Society; formerly county health commissioner; president of the Jay County Draft Board from 1917 to 1919; a captain in the 139th Field Artillery of the Indiana National State Guard; formerly postmaster; served as president of the board of directors of the Portland City Library; died in Indianapolis May 25, aged 77, of cardiovascular disease.

Markus Frederick Christian Bang Jelstrup, Big Lake, Minn.; Northwestern University Medical School, Chicago, 1903; on the staffs of the Deaconess Hospital, Grand Forks, N. D., and St. Luke's Hospital, Fargo, N. D., died April 10, aged 76, of coronary occlusion followed by angina pectoris.

Michael William Kapp, San Jose, Calif.; Cleveland Medical College, Homeopathic, 1895; member of the American Medical Association; retired member of the California Medical Association; formerly on the staff of San Jose Hospital; died May 28, aged 79, of paralysis agitans.

Thomas S. Kennedy, Eustis, Fla.; Hospital College of Medicine, Louisville, Ky., 1901; Spanish-American War veteran; served as sanitary officer of the West Florida district and assistant state director of rural sanitation; died May 25, aged 67, of massive gastric hemorrhage.

John Kimmel Kiser, Kittanning, Pa.; Cleveland Homeopathic Medical College, 1901; member of the American Medical Association; on the staff of the Armstrong County Hospital; died May 24, aged 69, of hemorrhages from ulcers.

Morris Henry Koch, Allentown, Pa.; Bellevue Hospital Medical College, New York, 1880; member of the American Medical Association; on the staffs of the Sacred Heart Hospital and the Allentown Hospital, where he died in May, aged 86, of senility.

Henry Alfred Lange, Providence, R. I.; College of Physicians and Surgeons, Baltimore, 1909; served in France for the American Red Cross during World War I; on the staff of the Homeopathic Hospital; died in the Rhode Island Hospital May 22, aged 60, of injuries received from a fall, polioencephalitis and hypertensive cardiovascular disease.

Herbert Wood Matthews, Penn Yan, N. Y.; Starling Medical College, Columbus, 1896; member of the American Medical Association; served during World War I; past president of the Yates County Medical Society; formerly chief of staff of the Soldiers and Sailors Memorial Hospital; died June 5, aged 72, of diabetes mellitus.

Frank Alexander May, Palmyra, Ind.; University of Louisville (Ky.) Medical Department, 1909; member of the American Medical Association; on the staff of St. Edward Hospital, New Albany, where he died May 2, aged 62, of postoperative mesenteric thrombosis and gangrene of the gallbladder.

Charles Walsh McQuillen ⊕ Charles City, Iowa; State University of Iowa College of Medicine, Iowa City, 1913; on the staff of the Cedar Valley Hospital; died May 30, aged 58, of heart disease.

John Tipton McVey, Bremen, Ohio; Ohio State University College of Medicine, Columbus, 1913; member of the American Medical Association; formerly vice president of the Fairfield County Medical Society; served on the staffs of the Ohio Hospital for Epileptics, Gallipolis, Massillon State Hospital in Massillon and the Columbus State Hospital in Columbus; on the staff of the Lancaster Municipal Hospital, Lancaster, where he died June 7, aged 61, of coronary occlusion.

Nathaniel Kingsbury Noyes ⊕ Plymouth, Mass.; Dartmouth Medical School, Hanover, N. H., 1890; a captain in the medical corps of the U. S. Army during World War I; health board physician in Duxbury from 1895 to 1925; visiting physician at the Jordan Hospital for many years; associate medical examiner of the Third Plymouth District for three terms; member of the Massachusetts Association of Health Boards and the Massachusetts Medico-Legal Society; died April 12, aged 80, of heart disease.

Arthur L. Payne, Eau Claire, Wis.; Medical College of Ohio, Cincinnati, 1890; died May 15, aged 79, of coronary thrombosis and diabetes mellitus.

Edward Rayburn Ridley ⊕ Detroit; University of Colorado School of Medicine, Denver, 1911; associate physician for the Detroit Edison Company; on the staff of the Harper Hospital, where he died May 30, aged 56, of heart disease and hypertension.

Harry Sloan Saks ⊕ Denver; University of Kansas School of Medicine, Kansas City, Kan., 1930; captain, medical reserve corps, U. S. Army, not on active duty; on the staffs of the Beth Israel, St. Anthony and Colorado General hospitals; died May 31, aged 39, of heart disease.

Frank Waldo Scott, Muskogee, Okla.; University of Nebraska College of Medicine, Omaha, 1910; served during World War I; served on the staffs of various Veterans Administration facilities and at the time of his death as chief of the outpatient and reception service, Veterans Administration Facility in Muskogee, where he died April 15, aged 57, of myocardial failure.

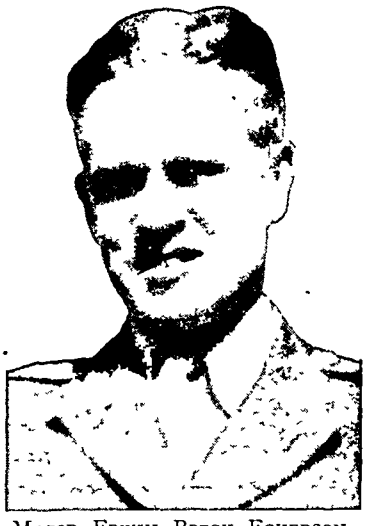
Arthur Edgar Smith, Cohoes, N. Y.; University of Vermont College of Medicine, Burlington, 1891; served in the medical corps of the U. S. Army with the rank of captain during World War I; died May 14, aged 81, of acute dilatation of the heart.

William D. Spearman, Social Circle, Ga.; University of Georgia Medical Department, Augusta, 1900; died April 30, aged 69, of angina pectoris.

Frank Spencer, Detroit; Michigan College of Medicine and Surgery, Detroit, 1900; member of the American Medical Association; died in St. Mary's Hospital May 19, aged 73, of bronchopneumonia.

Martin Frank Wright, Burlington, W. Va.; University of Maryland School of Medicine, Baltimore, 1890; member of the American Medical Association; served as president and secretary-treasurer of the Potomac Valley Medical Society and as vice president of the state medical association; in 1943 made honorary life member of the West Virginia State Medical Association; died June 21, aged 75, of cerebral hemorrhage

MARTYRS IN THE SINKING OF THE U. S. S. COMFORT



The Hospital Ship was attacked April 28 by a Japanese "suicide" pilot off the coast of Okinawa

CAPT. CHARLES D. CLARK, M. C., A. U. S., 1909-1945

CAPT. WILLIAM A. MACPHERSON, M. C., A. U. S., 1907-1945

MAJOR EDWIN BRECK ECKERSON, M. C., A. U. S., 1905-1945

Charles Dougherty Clark, South Bend, Ind.; Wayne University College of Medicine, Detroit, 1939; interned at the Grace Hospital in Detroit and served a residency at the Royal Oak Hospital in Royal Oak, Mich.; medical director of the Bendix Aviation Corporation; began active duty as a captain in the medical corps, Army of the United States, on July 1, 1942; aged 35

William Alexander Macpherson ✠ Downey, Calif.; College of Medical Evangelists, Los Angeles, 1935; interned at the Orange County Hospital in Orange; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Ophthalmology; served as assistant physician on the staff of the Sage Memorial Hospital in Ganada, Ariz., and on the staffs of the Los Angeles County Hospital in Huntington Park, the Bell Mission Hospital in Bell and the Suburban Hospital in South Gate; began active duty as a captain in the medical corps, Army of the United States, on Oct. 15, 1942; assigned to BTC number 5, Army Air Forces Technical Training Command in Kearns, Utah; aged 38

Edwin Breck Eckerson ✠ New York; Columbia University College of Physicians and Surgeons, New York, 1931; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons and the New York Academy of Medicine; member, New York Surgical Society; instructor in surgery at his alma mater; member of the board of directors and assistant attending surgeon at St. Luke's Hospital, where he served an internship; assistant attending surgeon at the New York Post-Graduate Medical School and Hospital and the Mount Vernon (N. Y.) Hospital; formerly resident at Lahey Clinic, Boston; began active duty as a captain in the medical corps, Army of the United States, on May 14, 1942; later promoted to major; chief surgeon on the U. S. S. *Comfort;* aged 39.

Ernest Foss Jr., Newburyport, Mass.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1941; interned at the Rochester General Hospital in Rochester, N. Y.; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 15, 1942 and assigned to the 19th General Hospital at Camp Livingston, La ; later promoted to captain; aged 31.

Wallace Lea Chesbro ✠ Lieutenant Commander (MC), U. S. Navy, Springfield, Mass.; Tufts College Medical School, Boston, 1938; interned at the Boston City Hospital; served a residency at the Robert Breck Brigham Hospital in Boston; began active duty as a lieutenant (jg) in the medical corps, U. S. Naval Reserve, on March 17, 1941; entered the medical corps of the regular navy as a passed assistant surgeon in the same rank on April 29, 1942; subsequently promoted to the ranks of lieutenant and lieutenant commander; aged 31.

John Francis O'Brien Jr., Waterford, Conn.; Georgetown University School of Medicine, Washington, D. C., 1943; interned at St. Francis Hospital in Hartford; began active duty as a first lieutenant in the medical corps, Army of the United States, on Oct. 6, 1944; trained at Carlisle Barracks, Pa., and at Moore General Hospital, Swannanoa, N. C.; aged 27.

CAPT. ERNEST FOSS JR., M. C., A. U. S., 1914-1945

LIEUT. COMDR. WALLACE L. CHESBRO (MC), U.S.N., 1913-1945

A MEXICAN TREATMENT FOR CANCER—A WARNING

To the Editor:—Many cancer patients from the United States have recently been attracted to Mexico City by reports of a new, allegedly successful method of treatment. We have taken occasion carefully to investigate the situation and we have prepared this statement of our opinion for the benefit of our colleagues who may be wondering about the matter.

Personal investigations reveal a modernistic building for hospitalization with inadequate laboratory or other scientific facilities. The physician in charge has a courteous and considerate bedside manner. We think that he makes his patients feel better by virtue of his personality. There is no positive evidence that he or his associates are successful by their peculiar methods in interrupting the usual course of a malignant process.

The theoretical bases for the method of treatment are extraordinary. While they make use of current scientific concepts, they are not in accord in any way with established biochemical or pathologic considerations. It is proposed that local sensitivity to pain is determined by the acid-base reaction of tissues. It is claimed that general sensitivity to pain can be estimated from urinary reaction. Alterations may then be made in diet or by medication, to change urinary p_H, in order to relieve sensitivity to pain. There is no objective satisfactory scientific evidence to support these ideas. In a similar way, a theory has been elaborated to cover various aspects of the control of malignant growth. Practically this results in the preparation of various glandular and tissue brews which are digested in various ways for parenteral and oral administration. No positive evidence exists to indicate the value of these preparations in treating malignancy.

A characteristic but unfortunate aspect of the matter is that no satisfactory clinical records are kept. Various statements are made from time to time in notebooks, but no attempt has been made, as far as we know, to provide clinical records that would be at all acceptable for clinical appraisal according to modern standards.

It is concluded that little benefit may result from cancer patients going to Mexico City for this new "treatment."

FIRST AID FOR IVY POISONING

To the Editor:—As one who is allergic to ivy poison, I was of course interested in the editorial in THE JOURNAL, June 23. Some thirty years ago I suffered from a violent dermatitis, which came on promptly after beginning to use my fur gloves that had been moth proofed with synthetic camphor. The discomfort was intense and resistant to everything I tried. The eruption was similar to that of an intense ivy poisoning. In desperation, after the condition had run on for about a week, I thrust my wrists under the stream from the hot water faucet, in and out quickly to avoid scalding. At first the itching was so much intensified that it was almost a pleasure, but each succeeding plunge brought less response, until the itching was entirely relieved after about a dozen applications and remained so for several hours. I repeated the same course of treatment, and the whole thing cleared up in a day or two. Following this clue, I tried the scalding hot water treatment in other cases of pruritus, including several of ivy poison, with the same result. A beginning case of ivy poison can be immediately stopped from itching and will dry and frequently will not even need a second treatment. I was infected several times this spring myself, as we have a lot of the stuff growing about my home. One treatment suffices to cure it and I do not give it a second thought. This has been my only treatment for this condition and it always works. I have used it with the same success in practically all the different forms of pruritus that have come under my care.

FRANCIS E. PARK, M.D., Boston.

DEVELOPMENT OF RED BLOOD CELLS

To the Editor:—I was interested in the answer to a question in THE JOURNAL, June 16, page 552, regarding the development of red blood cells, since it cites my 1938 article as the sole reference. There are, however, certain corrections and additions which are necessary in order to make your reply not only more accurate but also more practical and functional.

The idea set forth in the first sentence of your answer is essentially the one which some of us have been trying to put across for a number of years. However, the influence of Doan, Cunningham and Sabin has been so great during the past twenty years that it will be a long time before many of our largest and best medical schools realize the correctness of your first sentence. From personal experience in the East during the last eight years I would say that the majority of investigators do not believe that there are two generations of red blood cells.

The terminology which you suggest has been used by some of our histologists (Bloom) for a number of years and represents one of the schemes adopted by Maximow. However, clinical pathologists and general pathologists, especially in Europe, have been favoring the use of the term erythroblast alone in the general sense and not for a specific stage of red cell development. Not a few, but a vast majority, of authorities outside the United States use the term normoblast for all precursors of the definitive series. In our country there is a definite trend in that direction among the Midwestern clinicians, but not so with histologists. Such a classification has its merits when applied to a study of red blood cell development in pernicious anemia before and after treatment, where we recognize a megaloblastic series in the former and a normoblastic series in the latter.

The problem of red cell development is not solved, nor is it likely to be in the near future. Perhaps it is for the histologist but not so for the pathologist. For example, instances have been reported in which the patient, sometimes a child, appears to have a temporary or partial deficiency of anti-pernicious anemia principle. The red blood cell development does not seem to be either normoblastic or megaloblastic. Lambin and de Weerdt have described intermediate erythroblasts. I have been reluctant to recognize such a cell line until recently.

Any exposition of the red cell problem which cites my work as a reference would certainly be incomplete and inaccurate without some mention of the importance of nuclear structure as a means of cell identification. Bloom and his school have maintained that the greatest difference in appearance between the primitive and definitive generations is one of size. However, when dry smears are made of blood from the yolk sac, umbilical cord, fetal liver and bone marrow it is found that, regardless of cell size, the nuclear pattern is quite characteristic and distinctive. More and more emphasis should be placed on the value of nuclear structure in order for clinicians and pathologists to interpret properly blood and bone marrow cells.

OLIVER P. JONES, PH.D., Buffalo.
Professor and Head of Anatomy, University of Buffalo School of Medicine.

MORE ON MARIHUANA AND MAYOR LA GUARDIA'S COMMITTEE REPORT

To the Editor:—I read Dr. Bowman's communication, which appeared in THE JOURNAL, July 21.

There has come to my desk a reprint of an article from the *Indian Journal of Medical Research*, January 1942, entitled "Cannabis Sativa in Relation to Mental Diseases and Crime in India," by Col. Sir R. N. Chopra, who has been conducting a drug addiction inquiry for many years at the School of Tropical Medicine, Calcutta, India. Dr. Chopra is the author of "Tropical Therapeutics." The investigations by Dr. Chopra and his associates cover many years of scientific study, and their findings are representative of the entire population.

Some of Dr. Chopra's studies on hemp drug addiction in India were published in July 1939 in the *Indian Medical Research Memoirs*. His recent report on "Cannabis Sativa in Relation to Mental Diseases and Crime in India" is the result of long intensive study of 1,800 hemp drug addicts and destroys most of the conclusions of the New York Mayor's Committee, which studied, according to Bowman, 72 prisoners and 5 volunteers for a comparatively short period. The Chopra report indicates profound knowledge and prolonged study of the problem. Six hundred established cases of hemp drug insanity were studied and 1,238 hemp drug addicts were studied to show the relation between addiction to hemp drugs and crime.

The report summarizes that "excessive indulgence in narcotics, such as Indian hemp, is apt to produce in healthy individuals and in susceptible individuals mental confusion which may lead to delusions with disorientation and disordered movements. . . . Sometimes it may release subconscious impulses and lead to violent crime. . . . Inquiries in various jails and mental centers revealed that in quite a number of cases simple indulgence even in a single ganja or charas (marihuana) smoke was responsible for a heinous crime. . . . Fits of aggressive mania are not infrequently observed after indulgence in hemp drugs. Impulses of a suicidal and morbid nature have been known to occur. . . . Our studies in mental hospitals in the field (tables I and VII) and in prisons show that not infrequently addiction to hemp drugs was the immediate cause of a sudden unbalance of mind and the commission of a crime."

A copy of this article will be mailed free of charge to any one addressing a request to the U. S. Bureau of Narcotics, Tower Building, 14th and K streets N.W., Washington, D. C.

H. J. ANSLINGER, LL.B., Washington, D. C.
U. S. Commissioner of Narcotics.

WHOLE BLOOD AND CITRATED BLOOD

To the Editor:—Dr. Scannell's communication in THE JOURNAL, June 23, attempts to correct what he considers to be an error and brings to light a skeleton which most of us thought had been securely and permanently locked away in a closet.

The term "whole blood" has been most frequently applied to blood obtained from so-called live donors and administered by the direct method of transfusion. Others have applied the term to citrated or preserved blood. As has been pointed out repeatedly, both views are incorrect. Strictly speaking, whole blood must be a substance from which none of its component parts have been removed—cells, serum and/or plasma. Any of these components may be used separately according to indication, and they make up what might be referred to as whole blood but should simply be designated as "blood." When blood is mixed with an anticoagulant or preservative it might be called, as has been suggested, "modified blood."

The statement "Whole blood and citrated blood are as different as black and white" is therefore entirely erroneous. It serves only to create further confusion.

I must also take exception to the statement "severe reactions following the use of citrated blood are far more frequent than when whole blood is used." It is safe to state that most workers are now agreed that such is not the case. Certainly the literature affords ample proof to the contrary, and statistics of blood banks furnish further proof (Geiger, Jacob: History of Blood Transfusion, *Exper. Med. & Surg.* 2:83 [Feb.] 1944). May I quote from the annual report of the Lincoln Hospital Blood Bank for the year 1944:

Total number of transfusions	1,348
Modified blood (citrated bank blood)	1,018
Indirect blood transfusions (bank blood)	1,017
Direct blood transfusion ("live donor")	1
Pooled plasma (prepared from bank blood)	278
Resuspended cells	52
Reactions:	
1. Severe (hemoglobinuria in a case of hemolytic anemia)	1
2. Minor	
(*a*) Urticaria	12
(*b*) Pyrogenic	5
Percentage of severe reactions	0.07
Percentage of minor reactions	1.3

Finally I should like to point out that in Lincoln Hospital we instituted the practice of routine Rh determination in the latter part of the year. While the Rh factor may unquestionably be responsible for an occasional severe reaction, and while we heartily endorse this precautionary step, we cannot agree with the conclusion that, "as a result reactions have been eliminated when whole blood is used." Transfusion reactions can and must be kept at a minimum, but they must still be classified as (1) avoidable and (2) unavoidable. Let us concentrate on the avoidable reactions and not quibble about those that are unavoidable.

JACOB GEIGER, M.D., New York.

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, Aug. 11, page 1125.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written.* Various centers, Jan. 18. *Oral.* Various centers, Oct. Final date for filing application is Oct. 20. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 24.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* Chicago, May 27. Final date for filing application is Feb. 1. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago 12.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written. Part I.* Various centers, Feb. 2. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Oct. 2-5 and Los Angeles, Jan. 18-22. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 3-6. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written.* Locally, Oct. 19. *Oral.* New York, Dec. 7-8. Sec., Dr. C. A. Aldrich, 115½ First Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: *Written.* Various centers, Dec. 9. *Oral.* Chicago, February 1946. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Auricular Fibrillation with Myocardial Infarction.—Askey and Neurath studied 84 patients with auricular fibrillation observed among a group of 1,247 patients with myocardial infarction admitted to the Los Angeles County Hospital, an incidence of 7.7 per cent. The diagnosis of myocardial infarction was accepted only when the history and the electrocardiogram were typical. Auricular fibrillation was diagnosed only when confirmed by electrocardiograms. The mortality rate among patients with a myocardial infarction plus auricular fibrillation was much higher than in a group without auricular fibrillation. If the auricular fibrillation disappeared in one day, the mortality rate was slightly increased; if it persisted longer than one day, the mortality rate increased greatly. If no reversion to sinus rhythm occurred, death ensued in 89 per cent. One third of the deaths were due to systemic emboli. Persistence of arrhythmia could be correlated with preexisting cardiac damage. Cardiac damage, however, was not the sole cause of the high mortality rate and high incidence of embolism. Auricular fibrillation increased the mortality rate and incidence of embolism regardless of whether congestive failure was or was not present. Whether or not auricular fibrillation was found in the first electrocardiogram was a fairly reliable way of predicting whether the arrhythmia would be persistent or transient. In only 8 of the 55 cases in which auricular fibrillation was found in the first tracing did the arrhythmia disappear, whereas in 27 of 35 in which the arrhythmia followed myocardial infarction sinus rhythm returned. If the auricular fibrillation followed myocardial infarction, the prognosis was about the average if it disappeared in one day or less, but if it lasted more than one day the prognosis was much worse because then the arrhythmia persisted in about one third. The worst prognosis was among those whose auricular fibrillation was known to have existed before (99 per cent mortality with 57 per cent dying of systemic embolism) and among those who had a previous infarct (96 per cent mortality, with 30 per cent systemic embolism).

Gastrointestinal Symptoms of Heart Disease.—McMillan and his associates state that, when nausea and vomiting are dominant symptoms in a case of heart failure, one should not only consider as possible factors drugs, congestion of the abdominal viscera and disorders of the blood metabolites (such as occur in uremia) but should also entertain the possibility that progressive myocardial disease may be the cause of the symptoms. The mechanism of nausea and vomiting induced by progressive myocardial disease is believed to be analogous to that caused by digitalis, which has been shown to be due to a reflex arising in the heart itself. When coronary thrombosis occurs in a patient with preexisting narrowing of the smaller arterial branches a vicious cycle may ensue; the decline in the cardiac output and small pulse pressure lead to a further coronary insufficiency and progressive myocardial fibrosis, which brings about a further decrease in the cardiac output. In cases of heart failure in which there is a small pulse pressure with a high diastolic pressure, the outlook is poor.

Sulfonamide Therapy in Gonococcic Infection in Women.—Hesseltine and his associates report a four year study of sulfonamide therapy in gonococcic infection in women. They have treated 1,126 women with sulfanilamide, sulfapyridine, sulfathiazole or sulfadiazine. Criteria of cure required that patients be observed at least two months following therapy before they could be discharged as cured. A follow-up study was made on 575 patients who were discharged as cured or who failed to respond to therapy. Of these, 430 (75 per cent) responded to one course of therapy and were discharged cured; 145 had repeated or recurrent positive cultures and received further therapy. The authors arrive at the following conclusions: Sulfadiazine is the drug of choice for treatment of gonococcic infection of women. Sulfathiazole is slightly less effective. Both drugs gave better results and were better tolerated than sulfanilamide or sulfapyridine. Diagnosis of gonorrhea and criteria of cure, wherever possible, should be based on cultural studies. Patients should be observed through at least one negative menstrual period and preferably two. Negative smears and cultures taken just after the menstrual period should be required. Considerable information is obtained from cultures taken during therapy. The menstrual period is

the best provocative test. Complications of salpingitis or bartholinitis were not associated with more failures of therapy than acute uncomplicated cases. Drug fast strains were produced in the adult women in less than 1 per cent of the cases.

Duodenal Ulcer, with Perforation Following Cutaneous Burn. V. W. Koch and W. A. Fischer.—p. 719.

Bronchospirometry.—Pinner and his associates present a summary of the results of bronchospirometric studies which were pursued at the Montefiore Hospital, New York. The use of a soft rubber tube, instead of the metal bronchoscope, has made the method less uncomfortable and more reliable. Bronchospirometry is indicated whenever an irreversible operation on one lung is contemplated in order to determine the functional capacity of the contralateral lung. It also permits the study of various physiopathologic problems. Spirometry may give nearly normal findings on patients in whom bronchospirometry reveals extensive damage of one lung and compensatory changes in the other lung. X-ray and clinical findings do not permit definite conclusions as to pulmonary function. Pleural involvement often causes severe functional damage of the lung, whereas parenchymal lesions may have relatively little effect on pulmonary function. During pneumothorax treatment the collapsed lung shows the following changes: decrease of oxygen intake, minute volume, tidal air, vital capacity, reserve air and complementary air; increase of ventilation equivalent. Compensation is achieved by an increase of the oxygen intake in the contralateral lung. This is done only in part by increased ventilation; oxygen intake is further increased by a better utilization of the ventilated oxygen, i. e. a decrease of the ventilation equivalent. The contralateral effect of unilateral pneumothorax is manifested by a decrease of the vital capacity, reserve and complementary air of the contralateral lung. Thoracoplasty causes similar functional changes as does the pneumothorax but, on the average, these changes are less severe following thoracoplasty than those during collapse by pneumothorax and, at least in some cases, less severe than those in lungs following the abandonment of pneumothorax. Lungs reexpanded following pneumothorax treatment frequently show extensive functional impairment. Change in the patient's posture from the recumbent to the left or right side does not affect the percentage distribution of the vital capacity between the left and the right lung. Attempts at immobilizing a hemithorax by sandbags weighing up to 20 pounds and by strapping with adhesive tape do not achieve a reduction of the ventilation or respiratory work of the underlying lung.

Waldmann Vaccine for Foot and Mouth Disease.—Rushmore says that late in 1944 the Veterinary Corps of the Army of the United States produced and distributed 36,000 adult bovine doses of the vaccine. There has not been a reported incidence of the disease in any 1 of the 36,000 vaccinated animals. In Rome Province 15,000 dairy cattle and calves were vaccinated in September and October. During the first week in November a herd of 280 nonvaccinated dairy cattle and calves centrally located in Rome Province became infected, with a mortality of 20 calves and 7 cattle. Four months later none of the 15,000 vaccinated animals have reportedly shown any symptoms of the disease, though the infection was reported in 6 nonvaccinated dairy herds.

Ascorbic Acid Deficiencies in Rhesus Monkeys.—Shaw and his associates produced ascorbic acid deficiency in Rhesus monkeys. Acute deficiency could be produced in young monkeys in from thirty to fifty days. In the acute phase there was a precipitous loss of weight, slight tenderness of the joints and heavy residues on the tooth surfaces. No gingival changes were observed. When a single test dose of ascorbic acid was given, there was a rapid and complete alleviation of these signs. In the chronic state of ascorbic acid deficiency a series of gingival changes was observed which was accompanied by increasing food deposits on the teeth and dental tartar. There was severe tenderness and soreness at all the joints accompanied by a considerable swelling. Bone resorption occurred on the bone cartilage junctions, especially at the ends of the long bones of the legs. Late in the chronic deficiency period a severe loss of hair was observed, and there was some dermatitis. After a month of treatment with ascorbic acid there had been a moderate increase in weight, a great increase in activity and a loss of soreness about the joints. There had been no improvement in the hair coat. Both the loss of hair and the dermatitis could be cured or prevented by the administration of crystalline biotin. In 3 of the 6 chronically deficient monkeys there was a high incidence of dental caries. These data indicate that the signs of acute chronic ascorbic acid deficiencies in monkeys are distinctly different. They may partially explain the differences observed in experimentally produced and in spontaneous scurvy in man.

Serial Passage of Plasmodium Gallinaceum in Chick Embryos.—Haas and his associates have carried Plasmodium gallinaceum through fourteen serial passages by inoculating 10 to 13 day old chick embryos intravenously with parasitized blood. The infection produced in chick embryos by this method is highly fatal, with the majority of deaths from malaria occurring on the ninth day. There has been an overall mortality rate of 39 per cent within the first forty-eight hours after inoculation, apparently due to the difficulties inherent in the method. Enough embryos survive this early critical period to make the method a practical and reliable one for carrying this parasite in the chick embryo. The presence of a green color in infected embryonic membranes or fluids and in the liver and spleen of the embryo itself permits a ready and easy diagnosis of the presence of malarial infection and obviates the necessity for examining numerous blood films for parasites.

Growth of Pasteurella Tularensis.—Larson shows that Pasteurella tularensis grows readily on chick embryos when introduced into the yolk sac. Chick embryos are as susceptible as mice, and the concentration of organisms in the tissues and fluids of infected chick embryos approaches that obtained in infected mice.

*Tropical Eosinophilia: Report of Case. W. R. Hirst and W. J. McCann.—p. 1277.

Tropical Eosinophilia.—Tropical eosinophilia was first described by Weingarten as a disease apparently peculiar to the coastal areas of India. The syndrome is characterized by a gradual onset with malaise, weight loss, a low grade temperature, a paroxysmal dry hacking cough and physical findings similar to those of bronchial asthma. After several weeks a chronic stage is reached, at which time the patient may be subfebrile and the weight loss may cease, but paroxysms of coughing and wheezing may persist. The spleen may be palpable early in the febrile stage. X-ray examination of the chest in the febrile stage reveals a diffuse bilateral mottling of the lung fields, resembling the picture of acute miliary tuberculosis. Subsequent x-ray studies of the lungs reveal increased bronchial markings as in chronic bronchitis. There is massive eosinophilia. Hirst and McCann cite the history of a naval officer who had been on overseas duty in Central America and the Central and South Pacific islands exclusively. The patient had had symptoms of the disease for nearly two years. The dramatic response of the patient to arsenotherapy suggests a spirochetal or protozoan causation. The fact that the patient had never been in India suggests that either the disease exists endemically in the South Pacific area as well as in India or that it is transmissible directly from man to man. This syndrome should be considered in the differential diagnosis of any illness presenting a high eosinophilia. In cases with a massive eosinophilia, when no known cause can be found, a therapeutic trial of an arsenical may be warranted.

Congenital Deaf-Mutism.—Details observed in the study of deaf-mute children whose mothers were infected with rubella during pregnancy are presented. As the result of an appeal to doctors by the New South Wales Department of Public Health, 147 cases of congenital defects have been reported; in 102 of this series a history of maternal rubella was recorded. Of the children 74 are deaf. It has not been possible for Carruthers to tabulate the details of the whole series, but 17 patients have been under his private care. Analyses have been made to determine whether the stage of pregnancy at the time of infection of the mother or the intensity and duration of the mother's illness bears any relation to the nature and degree of congenital abnormalities subsequently to be found in the child. It seems likely that the importance of the stage of pregnancy at which infection occurs is that, if it is in the first six weeks, fetal damage will be widespread and may include the eyes, both divisions of the ears, the heart and perhaps many other parts. After the sixth week the eyes may escape, the heart may be spared and the semicircular canals may become normally developed; but the cochlea is still liable to be damaged, and the growth may be retarded. After the third month damage to the fetus is rare. Many of the children give some evidence of hearing over the tone range 512 to 2,048. In testing the caloric labyrinth reactions there was noted among others that none of the "rubella" group were made sick even when pronounced nystagmus was induced. The utricle and the semicircular canals do not appear to be left untouched by the maternal infection. Regarding associated defects, not 1 of the 17 patients has evidence of cataract. No evidence of ductus arteriosus was observed, but stunting of growth is evident in 11 of 17 patients and microcephaly in 3.

*Treatment of Postarsphenamine Jaundice with Sulfur-Containing Amino Acids. R. A. Peters, R. H. S. Thompson and A. J. King, D. I. Williams and C. S. Nicol.—p. 35.

Treatment of Postarsphenamine Jaundice.—Peters and his associates say that, although infection has long been regarded as a probable factor in the etiology of many cases of postarsphenamine jaundice, the arsenicals themselves have never been exonerated. It has been shown repeatedly that the administration of different arsenical compounds to experimental animals can produce damage and necrosis of the liver cells in the absence of coincident spirochetal or other infection. Since a high protein diet can prevent bilirubinemia and liver damage in dogs after weekly intravenous injection of oxophenarsine hydrochloride, it was decided to study the effect of the oral administration of certain sulfur-containing amino acids on the course of postarsphenamine jaundice. The authors studied 468 cases of postarsphenamine jaundice. The conclusions are based on the treatment of 150 severe cases selected from the total of 468. Three groups of patients were treated respectively with cysteine, methionine and casein, control patients being observed simultaneously throughout. The rate of recovery of the patients was observed clinically and by serial estimation of the serum bilirubin levels. A slight but statistically significant increase in the rate of return to normal was noted in the patients receiving cysteine or methionine. Casein, in the dosage used, did not bring about any beneficial effect.

*What One Can Expect of Surgical Therapy of Essential Arterial Hypertension. C. Patiño Mayer, L. Lepera, F. A. Pataro and V. F. Pataro.—p. 469.

Sympathectomy in Essential Arterial Hypertension.—Patiño Mayer and his collaborators report good results from sympathectomy followed by potassium thiocyanate therapy early in the phase of malignant essential hypertension and of sympathectomy in essential hypertension with moderate sclerosis with or without spasticity. Blood pressure in his cases returned to normal and remained normal up to date, two or three years after the operation. Symptoms of increased intracranial pressure and of cardiac, renal and pulmonary disturbances and nervousness were greatly diminished. The prognosis as far as the comfort and duration of life is concerned was much improved.

Treatment of Ulcerative Disease. T. M. Rybakov.—p. 3.
*Symptomatology of Prescorbutic States. M. T. Arinkin.—p. 9.
*Dry Serum Therapy in Albumin Deficiency States. A. A. Bagdasarov, M. S. Dulcin, P. M. Alperin, V. V. Vinogradov and F. E. Loginova.—p. 15.

Symptomatology of Prescorbutic States.—According to Arinkin, one of the first objective symptoms in the incipient stage of scurvy is pallor of the skin and of the conjunctiva. The pallor is probably caused by a spasm of the peripheral blood vessels or by alterations in the blood itself. In the more advanced stage there is pain and tenderness about the joints, particularly of the lower extremities, with a still later appearance of periarticular swellings and discoloration due to hemorrhages into the deep tissues. Some patients complain only of bleeding gums. The author studied 14 patients from 14 to 27 years of age with manifestations of the incipient stage of scurvy. Study of the peripheral blood of these patients revealed insignificant alterations on the part of the red cells, such as mild hypochromia and mild erythropenia. The sternal punctate, however, showed an abnormal increase in the number of microblasts and normoblasts. In the author's experience, in all anemic states, with the exception of aplastic anemia, there exists a parallelism between the degree of anemia and the hyperplasia of the erythroblastic tissue of the bone marrow: the more severe the anemia of the peripheral blood, the greater the percental content of nucleated reds in the bone marrow. This hyperplasia of the erythroblastic tissue of the bone marrow in the preanemic state of scurvy is an index of general intoxication of the organism.

Dry Serum Therapy in Albumin Deficiency States.—Bagdasarov and his associates employed transfusions of dissolved dry human serum in the treatment of clinical states characterized by albumin deficiency. The advantage of this method is that the serum can be given in concentrated solutions with albumin content as high as 28 per cent. Such a serum should exert a favorable effect on osmotic pressure, the water exchange and the tendency to edema. Addition of glucose to the solution increases its effectiveness. The authors administered 170 transfusions to 30 patients with manifestation of alimentary disturbances characterized by symptoms of albumin deficiency, increased capillary permeability and manifestations of hypovitaminosis, chiefly of B_2 and B_1. The dry serum was diluted in concentrations amounting to from two to four times the normal relationship and given every three or four days in amounts varying from 50 to 100 cc. The post-transfusion reactions were few and, when present, were mild. The therapeutic effect was both pronounced and persistent. There was an initial increase followed by decrease in diuresis, disappearance of edema, increase in weight, improvement in muscle tone, termination of diarrhea and normalization of the blood picture. Five patients with alimentary edema treated with repeated small transfusions of conserved blood responded well to this treatment, but the therapeutic effect was not as definite as in the cases treated with concentrated serum solution, particularly with regard to normalization of the albumin content of the blood.

Respiration in Hypoglycemia.—Lundbaek describes a characteristic type of respiration which occurs during severe hypoglycemia and which has been observed in connection with metabolic experiments. This type of breathing is characterized by the occurrence of varying depth of respiration, jerky expirations and postinspiratory and postexpiratory pauses. This type of respiration is due to a general hypo-oxidation of the cerebrum resulting from hypoglycemia. The hypoglycemic type of respiration may become important in the differential diagnosis between diabetic coma and insulin reaction.

Renal Changes in Fatal Sulfathiazole Damage.—Bergstrand describes the pathologic changes in 7 cases in which sulfathiazole damaged the kidneys. At least 5 of these patients died of uremia. The changes were the same in all cases. They were characterized by focal destruction of the uriniferous tubules at the sites at which sulfathiazole crystals had precipitated. Hyaline protein deposits with perifocal round cell infiltration and hemorrhage were observed around the sulfathiazole crystals in the destroyed tubules. These gave the microscopic picture a characteristic appearance. The renal pelvis showed destruction of epithelium, hemorrhages, and inflammatory cell infiltration in the wall and in the fat of the hilus. The author suggests that inflammatory edema of the kidneys and urinary passages, which was produced by precipitated sulfathiazole crystals, was the chief cause of the uremia.

Are Red Blood Corpuscles in Adults Formed from Erythroblasts? Lisa Boström.—p. 805.

Paroxysmal Tachycardia in Infants.—Christensen says that 37 cases of this disorder in infants have been reported; 7 were in the first week of life, 19 in the first month. About 100 cases in childhood have been reported. Two additional cases in infants aged 3 weeks and 6 months respectively are described. The onset is usually characterized by listlessness, restlessness, loss of appetite, vomiting and diarrhea, with a gradually affected general condition. The cardiac rate during attacks is from 250 to 300. There may be symptoms of heart failure, possibly collapse, convulsions and unconsciousness. There was a congenital heart defect in only 3 of the 37 cases, all fatal. When no organic heart changes are found, the disturbance probably depends on failure of the central or autonomous regulation of the heart. In older children the attacks are more often caused by diseases which have led to injury of the myocardium or of cardiac innervation. The prognosis is good in uncomplicated paroxysmal tachycardia. Digitalis, strophanthin and mecholyl are the most effective drugs.

Roentgen Examination for Pulmonary Tuberculosis as Routine Examination in Hospitals. U. Gad.—p. 837.
Relation Between Clinical Symptoms and Results of Gastroscopy in Patients with Achylia: Gastroscopic Studies, VI. T. Christiansen.—p. 838.

Parenteral Iron Therapy.—The indication for this therapy, intravenous as well as intramuscular, is hypochromic anemia when all other treatment has been ineffective. Intragluteal injections of 11.95 mg. of metallic iron every second or third day gave good results in the 8 cases reported, 2 of which were of anemia after infectious disease, 2 of cancer anemia and 2 of simple anemia. The iron concentration in the serum rose slowly. There were no toxic symptoms. In spite of the immediate by-effects of intravenous iron therapy this method may be more agreeable to the patient than the intramuscular, which seems to give more rapid results but has the drawback of often causing protracted pain at the seat of the injection. Because of the toxicity of iron salts, daily doses above not quite 12 mg. of metallic iron should not be given.

*Diagnostic Value of Chlorine Ion Content in Cerebrospinal Fluid and Relation Between Chlorine Ion in Cerebrospinal Fluid and in Blood. F. Karlström.—p. 839.
Thyrotoxicoses. John Hertz.—p. 856.
Allergy, Hypersensitivity to Histamine and Treatment with Histamine in Various Forms of Headache, Especially Migraine. B. Chronholm.—p. 865.

Chlorine Ion in Cerebrospinal Fluid.—Karlström's material comprises 428 cerebrospinal fluids from 355 patients. In acute poliomyelitis, epilepsy and other diseases of the central and peripheral nervous system the chlorine ion and sugar content of the cerebrospinal fluid and the chloride and sugar index in the blood are within normal limits. In tuberculous meningitis and bacterial (not tuberculous) meningitis the chlorine ion and sugar content of the cerebrospinal fluid and the blood chloride and blood sugar index are lower than normal. Extremely low values for the chlorine ion content of the cerebrospinal fluid point either to tuberculous or to bacterial meningitis; a value lower than 526.5 mg. of sodium chloride per hundred cubic centimeters is pathognomonic for tuberculous meningitis.

Renal Changes in Myeloma.—Study of the unusually large material of 22 cases of myeloma, Lagercrantz says, shows that there is probably a connection between Bence Jones albuminuria and the renal changes in myeloma. The constant changes in myeloma are injury to the tubular epithelium, but the characteristic feature of the disease is the abundant, probably secondary formation of large compact albumin cylinders which block the tubuli, cause inactivity atrophy of the nephrones and stimulate formation of giant cells. In the later stages of the disease a contracted kidney develops.

Book Notices

Penicillin and Other Antibiotic Agents. By Wallace E. Herrell, M.D., M.S., F.A.C.P., Assistant Professor of Medicine, the Mayo Foundation, Rochester, Minn. Cloth. Price, $5. Pp. 348, with 45 illustrations. Philadelphia & London: W. B. Saunders Company, 1945.

A noteworthy accomplishment of the war effort in relation to medicine has been the development of antibiotic therapy. This applies especially to penicillin. Although the advances have been phenomenal, adequate information concerning the therapeutic indications of penicillin has been made available to the medical profession, as well as other pertinent knowledge. Nevertheless in such a rapidly developing field a crystallization of the subject in the form of a monograph is desirable, with the realization, however, that such an effort may be superseded in the near future by information not available at present.

Herrell has endeavored to summarize the extensive fundamental and clinical studies on penicillin and other antibiotic agents. The first hundred pages are devoted to the basic investigations on penicillin. This includes a historical survey; methods of preparation; its physical, chemical and antibacterial properties; absorption, diffusion and excretion, and assay methods. Precise information concerning the chemistry of penicillin is not available, and probably the mechanism of its antibacterial activity is not known.

The succeeding 150 pages are devoted to the clinical use of penicillin. In the main there will be general agreement with the recommendations. Herrell is an enthusiastic advocate of the continuous intravenous method for administering penicillin, particularly to patients with severe infections. His objection to the intermittent, intramuscular mode of injection is that it causes local discomfort and that abrupt rises and falls in blood concentration are not desirable in the therapy of severe infections. One need not utilize 2 to 4 cc. of isotonic solution of sodium chloride for an injection of 10,000 to 20,000 units of penicillin. Most preparations of penicillin now available can be readily dissolved in saline solution, so that only 0.5 to 1 cc. is necessary for such doses. The more convenient intramuscular method may be employed successfully for the treatment of even the severest infections, provided adequate amounts of penicillin are used.

The widest application of penicillin has been made in the management of war wounds, both prophylactically and therapeutically. Several excellent reports have recorded the results in detail. This experience will be of considerable aid in civilian practice. It is unfortunate that more emphasis along these lines has not been incorporated within this monograph. The last section is devoted to other antibiotic agents such as tyrothricin, streptothricin, streptomycin and the less important preparations. The discussion on tyrothricin is one of the best reviews that has appeared. Although interest at present is focused on streptomycin, only twelve lines are devoted to clinical results and no final conclusions are made.

The text is presented in a concise and lucid manner. Each of the twenty-five chapters concludes with key references to the literature. Considering the wartime restrictions, the format, type, grade of paper and the reproduction of illustrations are excellent.

G. I. Nightingale: The Story of an American Army Nurse. By Theresa Archard, Captain, A. N. C. Cloth. Price, $2.50. Pp. 187. New York: W. W. Norton & Company, Inc., 1945.

Captain Archard's story is a story of a typical American girl and her companions, all army nurses. She takes us with her from an American home through a year's "training for defense," through the shock of Pearl Harbor. With her we embark for "overseas." We experience the tedium of waiting, the excitement of unknown perils which lie ahead. We "shake down" our organization—we embark for unknown destinations and finally wade ashore in an amphibious landing. With her we experience the fear, the thrill, the excitement of battle and exult in the justified pride of our task well done. With her and her unit we advance and retreat and advance with the tide of battle. We experience the thrill of a life saved by skill, of comfort and surcease from pain through the work of our hands. In her story we see what a well organized team of doctors, nurses and enlisted men can do for the relief of suffering and the prevention of death, even under the most trying circumstances. In her story we have the record of the 48th Surgical Hospital, which did so much with so little and finally spent itself in its work for its patients, but in so doing pointed the way for the many others which followed it.

The story is authentic. Captain Archard has captured the moods of the men and women who make medical history in the armed forces. She calls her story "G. I. Nightingale." "G. I." is commonly interpreted as "Government Issue"; it might well be paraphrased "Granite, Iron," for the women of this historical record are made of rigid stuff. Florence Nightingale would be truly proud of her successors.

How parallel is this record with that of Florence Nightingale in the Crimea! As Florence Nightingale brought cleanliness to Scutari and reduced its death rate from 47 per cent to 2 per cent, so do our nurses bring cleanliness to our improvised military hospitals around the world and in so doing make it possible for those who have fallen in battle to rise up and walk the earth again.

This story illustrates woman's great contribution to modern medicine. It shows at its best that unbeatable team the Doctor and the Nurse.

It is a story of hard work, of winning against great odds; but through it all Captain Archard never loses her sense of humor. She laughs at her fears, she laughs at her plights, she laughs at herself and her nurses in soldier's coveralls. She laughs at her skinny body wasted from short rations and North African malaria.

Técnica e tática na calculose do hépatocolédoco. Por Piragibe Nogueira, Docente livre de Clinica cirurgica da Faculdade de medicina da Univer-sidade de São Paulo. Paper. Pp. 117, with illustrations. São Paulo, 1944.

In this work, which is Dr. Piragibe's thesis presented to the Faculty of Medicine of São Paulo in partial fulfilment of the right to conduct courses in operative surgery at the medical school, the author summarizes his experience in dealing with hepaticocholedochal lithiasis, besides discussing the literature. It is a concise synopsis on the subject, with 140 references.

The monograph is divided into eight chapters, on history, definition, anesthesia, surgical anatomy of the biliary ducts, access to the biliary ducts, exploration and operative technic, secondary operations and case reports, conclusions and references. In the chapter on surgical anatomy the author describes the various pitfalls that exist in operating on the gallbladder, illustrating the different anomalies that can be found in the ducts, their blood supply and their relation to the hepatic blood vessels. Dissection on cadavers substantiates the author's statements. Although no personal statistical data are given and only case reports are published, the author shows experience in this field; he is of the opinion that operative cholangiography is of value but not an essential means of exploration in the hands of an experienced surgeon who can make good use of palpation, probing and irrigation for assuring patency of bile ducts.

A Study of Certified Sickness Absence Among Women in Industry. By S. Wyatt, assisted by R. Marriott, W. M. Dawson, Norah M. Davis, D. E. R. Hughes and F. G. L. Stock. Medical Research Council, Industrial Health Research Board, Report No. 86. Paper. Price, 9d. Pp. 34, with 4 illustrations. London: His Majesty's Stationery Office, 1945.

This investigation substantiates in large measure American experience in the employment of women. Twenty thousand women were observed. Respiratory, digestive and functional nervous disorders were most serious offenders. Gynecologic disorders are relatively unimportant as reflected in average days of sickness per worker, but in average length of individual absence they rank first in the married group and second in the single. Seven and eight tenths per cent of the total work days were lost. Married women lost 17.4 days, single women 10.6. Conditions of work had recognizable effect on sick absence. The importance of good medical and attendance records in industry is stressed. Although these studies were carefully controlled and based on certified absences of two days or more, there are many factors which affect lost time not directly assignable to health but which nevertheless are reflected in the statistics.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SIGNIFICANCE OF LOW BASAL METABOLIC RATE —THYROID EXTRACT AND VITAMIN B.

To the Editor:—Does taking thyroid, either the right amount or an overdosage, take up the vitamin B from the system? What conditions other than hypothyroidism would account for a low basal metabolic rate?

George A. Bakke, M.D., Oakland, Calif.

ANSWER.—The administration of desiccated thyroid and the presence of hyperthyroidism appear to increase the requirement of the body for vitamin B. However, if the diet is well balanced and adequate in amount supplementary therapy with B complex is not necessary. It has been suggested that the administration of vitamin B_1 to patients with hyperthyroidism is valuable in improving their preoperative condition. The evidence for this statement is not convincing.

There is a large group of patients with basal metabolic rates of —15 to —25 per cent who do not appear to have hypothyroidism. When their rates are increased by the administration of desiccated thyroid these patients become nervous and suffer from palpitation, indicating that the slight depression in their level of metabolism may not be the result of hypothyroidism. An important cause of low basal metabolism is, of course, hypopituitarism, but in this condition the low metabolism is a result of hypothyroidism which develops secondary to the pituitary deficiency. In patients with this abnormality, raising the metabolism by the administration of thyroid produces definite improvement but does not correct many of the abnormalities that are not related to the hypothyroidism, as, for example, the hypogonadism.

In patients with myxedema the basal metabolism may be raised to normal with dinitrophenol without producing any effect on the myxedematous condition. Observations such as these indicate that there may be many factors controlling the total metabolism that are not clearly understood at present. When one is faced with the problem of determining whether or not hypothyroidism is present, the best thing is probably to make a therapeutic trial of administering thyroid. If improvement occurs when enough is given to raise the basal metabolism to normal it may be concluded that hypothyroidism is the cause of the low rate. If improvement does not result, it may be concluded that hypothyroidism is not present and the administration of thyroid may actually be harmful.

TOXICITY OF PARALDEHYDE AND INSOMNIA

To the Editor:—What is the effect of prolonged daily administration of paraldehyde in doses of 8 to 16 cc.? Is this likely to produce toxic symptoms or harmful effects? I have a patient who suffers from insomnia and this is the only thing that produces sleep now. She has taken barbital and its derivatives in doses of 10 to 20 grains almost daily for the past ten to fifteen years, and it no longer produces the desired result. She has been treated by prominent psychiatrists without definite effect. At that time she was getting results with barbital, and they told her she would have to continue it the rest of her life. I know that continued use of paraldehyde is likely to produce chronic poisoning with symptoms similar to chronic alcoholism, but what about the toxicity in regard to internal organs? Has paraldehyde been administered over indefinite periods without harmful effects? Can any other drug be suggested for this patient? Chloral hydrate has been tried. What will disguise the odor of paraldehyde on the breath? M.D., South Carolina.

ANSWER.—The chronic toxicity of paraldehyde is not well known but is generally stated to be similar to that of alcohol, including the mental aberrations. Tolerance may develop. A postmortem examination of a man who had taken 4 to 8 cc. of paraldehyde daily for several months, and 75 cc. or more on his final night, showed principally hyperemia of the stomach and upper intestine, without any severe visceral degenerations (McFall, J. E. W.: Paraldehyde Poisoning, *Brit. M. J.* **2**:255 [Aug. 8] 1925). There is no way to disguise the odor of paraldehyde on the breath. Nightly sedation for insomnia is unwise. Daytime problems carried over into the night, or a simple habit of inversion of sleep, may be responsible and should be approached from the psychotherapeutic standpoint, if possible. Rather than substitute another drug for a person who is obviously easily habituated, a period of institutional care under a psychiatrist is suggested.

COUGH REMEDIES

To the Editor:—I have been accustomed to prescribe guaiacol carbonate or terpin hydrate for coughs that were or showed a tendency to become chronic. Now these two drugs are discontinued because they were deleted from the U. S. Pharmacopeia. What is recommended in their place?

M.D., New York.

ANSWER.—So far as is known guaiacol carbonate and terpin hydrate are still official in the National Formulary and the U. S. Pharmacopeia. Guaiacol carbonate is highly insoluble and probably inactive with respect to cough. Terpin hydrate, although of long empiric usage, also is of questionable value either to reduce or to lessen cough.

When coughing is unproductive and associated with a "tickle" in the throat, any substance with a strong local action is likely to bring relief. Sweet, alcoholic preparations with a pungent taste are effective. One such agent is Elixir of Terpin Hydrate, N. F., to which the terpin hydrate presumably lends only flavor. Others are Aromatic Elixir, U. S. P., and Elixir of Glycyrrhiza, U. S. P.

When the cough is persistent, and especially if it is productive, suppression is indicated but should be intermittent, to allow drainage of the bronchial tree on the one hand and yet prevent the fatigue of constant coughing. For this purpose codeine is the agent of choice in doses of 15 mg. administered every three or four hours. It is preferably dispensed in liquid form, to obscure the bitter taste, and to add to the local effect in the mouth and throat. For this purpose any of the vehicles previously mentioned may be used.

Like terpin hydrate, sodium iodide and ammonium chloride are drugs of long usage in cough, particularly with the intent of thinning tenacious sputum. Here also the alleged effect appears to be greatly exaggerated over that actually produced.

POSITIVE WASSERMANN REACTION AND BOECK'S SARCOID

To the Editor:—What is the significance of a 4 plus Wassermann reaction in the presence of Boeck's sarcoid? What is now considered to be the best form of treatment? What is the prognosis? M.D., Oklahoma.

ANSWER.—Boeck's sarcoid is regarded by some investigators as an atypical form of tuberculosis, although others disagree with this view. Placing it in the group of inflammatory diseases, one must consider the possibility of a false positive serologic reaction for syphilis. B. D. Davis (Biologic False Positive Serologic Tests for Syphilis, *Medicine* **23**:359 [Dec.] 1944) has studied this problem very thoroughly. Among the diseases listed in which such a false positive test may occur are tuberculosis and miscellaneous infections. Davis also outlines the requirements for a verification test. Therefore, control studies (Kahn test, quantitative Wassermann test) are indicated in a case of Boeck's sarcoid with a 4 plus Wassermann reaction before definitely establishing the clinical diagnosis of syphilis. In this connection it is interesting to note that quite frequently hyperglobulinemia is found in patients with Boeck's sarcoid. However, as Davis points out, "there appears to be a widespread but unwarranted impression that false positive serologic tests are often caused by any conditions which give rise to a marked hyperglobulinemia."

Treatment of Boeck's sarcoid has usually been purely empirical and includes the use of arsenicals, tuberculin, iodides, gold salts, hyperpyrexia, ultraviolet irradiation, roentgen rays and radium. The latter have been successful in the treatment of skin lesions, particularly in the Darier-Roussy type, and also in the Boeck lesion. Evaluation of any form of treatment is difficult because of the tendency of the lesions to spontaneous resolution. Earlier workers have not found roentgen therapy of benefit in the systemic lesions. Middleton sums up this experience in the latest edition of Cecil's Textbook of Medicine with the statement that roentgen and radium therapy offer nothing in this disease. Recently, however, several reports on the treatment of enlarged lymph nodes and of hilar and pulmonary sarcoid have been favorable. Pohle and his associates (Pohle, E. A.; Paul, L. W., and Clark, Elizabeth A.: Roentgen Therapy of Boeck's Sarcoid, *Am. J. M. Sc.* **209**:503 [April] 1945) recommend moderate doses of roentgen rays applied either to the mediastinum or to the involved lymph glands, using the same technic as is customary in the treatment of inflammatory disease. Eight of their 14 cases were observed sufficiently long to permit at least preliminary conclusions: in 4 of the first 8 cases the therapeutic result was good, in 1 instance excellent, in 1 satisfactory and in 2 only fair. Untoward reactions were not observed in any one of their treated cases.

UNITED STATES NAVAL RESERVE

In the course of many years the therapeutic usefulness of salicylates has become well established. With dosages within reasonable limits, the untoward reactions which sometimes have developed always have been of minor importance. Recently, however, several papers and editorials have appeared which suggest that even with relatively small doses of salicylates the tendency to hemorrhage is increased; this tendency is indicated by the fall in the prothrombin content of the blood and, in some instances, by an increase in the blood coagulation time.[1]

During the treatment of large numbers of young adults with active and inactive rheumatic fever hemorrhagic tendencies have been noted infrequently in this hospital, and even when this tendency has occurred it did not appear to be correlated with the administration of salicylates. This broad clinical impression was so divergent from those results recently reported that a control study was undertaken to determine primarily the effect of salicylates administered orally on the level of prothrombin in the blood. Secondarily it was thought useful also to correlate the salicylate level in the blood with any change in prothrombin levels that might occur and to observe the effect of such salicylate levels on the liver, sedimentation rate, blood count and renal function.

From the Rheumatic Fever Unit of the United States Naval Hospital, Corona, Calif.

Lieutenant Butt is on leave of absence from the Division of Medicine, Mayo Clinic, Rochester, Minn.

Ensign W-V(S) Rosalie Ruth Ryan, U.S.N.R., supervised and aided in the laboratory procedures used in this study, and Ruth F. Stribey, HA2/c, U.S.N.R., aided in making the charts.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the United States Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

H., and Campbell, H. A.: Studies on 'rothrombinopenic Effect of Salicylate in Man, & Med. **53**: 251-254 (June) 1943.

PLAN OF STUDY AND METHODS

The group for study comprised 113 young men who were afflicted with rheumatic fever. The large majority of these patients at the start of the study had inactive rheumatic fever and were ambulatory; a small group (22) were having a recurrence of active polycyclic rheumatic fever at the start of the study or had one during the study. All of the 113 patients were given the same general diet furnished by the Navy and all except those who were confined to bed were allowed to continue their usual routine activities under military supervision. Arbitrarily the 113 patients were divided into two groups. One group of 57 served as controls. The remaining 56 were given varying daily doses of salicylates for four weeks, while the 57 control patients were given orally only sodium bicarbonate in varying doses during the same period of time.

During the first week the 56 patients who received salicylates were given 25 grains (1.6 Gm.) of sodium salicylate orally together with 10 grains (0.65 Gm.) of sodium bicarbonate twice daily; the controls received only 10 grains of sodium bicarbonate twice daily. The medication given to both groups during the four weeks is listed in the accompanying table. No medication was administered during the fifth week to either group of patients except for a few who still remained ill.

During the study 5 of the 56 patients receiving salicylates had to discontinue their medication and were dropped from the study. Two of the 5 developed acute appendicitis, 1 required confining disciplinary action and 2 developed severe nausea and vomiting. The results, therefore, are based on study of only 51 patients who received salicylates. Only 3 of the controls had to be eliminated from the study. One of the 3 required an operation for severe cellulitis of the leg, 1 required disciplinary action and, after careful study of the third, it was decided that the correct diagnosis was rheumatoid arthritis and not rheumatic fever. The final results concerning the controls represent data from 54 patients.

The prothrombin content of the blood was measured by modification of the method first proposed by Quick in which the prothrombin time of whole plasma is measured in seconds.[2] During the course of this experiment more than 1,500 prothrombin times were determined and certain observations were made that would be evident only in such a large group. The factors of

2. Magath, T. B.: A Method for Determining the Prothrombin Clotting Time, in Walters, Waltman, and Snell, A. M.: Diseases of the Gallbladder and Bile Ducts, Philadelphia, W. B. Saunders Company, 1940, pp. 563-564.

time, room temperature and kind of thromboplastin used were found to be extremely important. Determinations on normal controls were done at the beginning, middle and end of the series of determinations on the two groups of patients. On one or two occasions it was necessary to record a longer normal prothrombin time for the half of our group of patients whose tests were run last. The prothrombin times on the patients receiving sodium salicylate were always determined before those on the "control" patients. This procedure lessened any effect of greater lapse of time on the prothrombin time of this group of patients. Experiments showed that on a typical hot southern California day the prothrombin time was lengthened from one to four seconds if the plasma stood for two hours, and if the plasma was allowed to stand even longer the prothrombin time was proportionately increased. Stored plasma from the plasma bank showed no prothrombin activity. The source of thromboplastin used for the tests varied. From June 14 to June 25, 1944 dried rabbit brain prepared by Magath's method was employed. From June 26 to July 7 Bacto Thromboplastin as prepared by the Difco Laboratories was used, and from July 8 to July 26 fresh rabbit lung prepared by the method outlined in the "Clinical Chemistry Notes of the Naval Medical School" was employed. These frequent changes in source of thromboplastin were undesired but forced by necessity of obtaining material. Diluted plasma (12.5 per cent) was tried, but the rather indefinite end point led us to discard this method. To rule out individual variations in so-called normals, our daily normal values were determined from the blood from two or three members of the laboratory staff.

Plan for Administration of Drugs

Time	Control Group	Patients Given Sodium Salicylate
First week	10 grains (0.65 Gm.) of sodium bicarbonate 2 times a day	10 grains of sodium bicarbonate plus 25 grains (1.6 Gm.) of sodium salicylate 2 times a day
Second week	10 grains of sodium bicarbonate 4 times a day	10 grains of sodium bicarbonate plus 25 grains of sodium salicylate 4 times a day
Third week	10 grains of sodium bicarbonate every 4 hours day and night	10 grains of sodium bicarbonate plus 25 grains of sodium salicyl ate every 4 hours day and night
Fourth week	10 grains of sodium bicarbonate every 4 hours day and night	10 grains of sodium bicarbonate plus 30 grains (2 Gm.) of sodium salicylate every 4 hours day and night
Fifth week	No medication	No medication

The sedimentation rate was measured by the method of Westergren. Liver function was measured by the intravenous sulfobromophthalein method;[3] the blood samples were taken at intervals of five and thirty minutes after injection of 2.5 mg. of sulfobromophthalein per kilogram of body weight. The serum bilirubin was measured by the method of Malloy and Evelyn[4] and the van den Bergh reaction by the method described by Kolmer and Boerner.[5]

The method outlined by Brodie, Udenfriend and Coburn[6] was used for the determination of blood salicylates. A few minor changes were made to allow the work to be done more conveniently in the necessarily large volumes of the experiment. It was more convenient to use serum rather than the plasma recommended by the authors. A large series of comparative studies on the salicylate content of plasma and serum was run and the difference of + or — 2 mg. per hundred cubic centimeters was considered insignificant. Owing to the difficulty of obtaining a large supply of Pyrex glass stoppered bottles, an attempt was made to find an adequate substitute. The common 4 ounce "French Square" bottle with a bakelite screw cap was highly satisfactory and is in wide use in pharmacies. The inner layer of cork and paraffin in the bottle cap must be removed before use. Screw caps of plastics other than bakelite are dissolved by ethylene dichloride and therefore cannot be used. The ordinary Kahn shaker in use in most clinical laboratories is adequate for shaking the mixture and has the additional advantage of holding thirty-six to fifty bottles.

There is no loss of salicylates by allowing the blood to stand overnight, and the procedure may be interrupted at any point for a considerable length of time. Ethylene dichloride is toxic and should be used only with forced ventilation. Since ethylene dichloride should not be pipetted, a tapered small graduated cylinder holding 30 cc. was found suitable for measuring the chemical for the purpose of the test.

In ten days prior to the start of the study all 113 patients had the routine tests just described. The prothrombin time was determined three times and the sedimentation rate twice during this period. All prothrombin times were well within normal limits. The sedimentation rates of a few patients were elevated. During the four weeks of the study the concentration of hemoglobin, number of erythrocytes and leukocytes, urinalysis, dye retention test, serum bilirubin and van den Bergh reaction were determined once weekly on the 51 patients who were receiving sodium salicylate. The Quick prothrombin time was determined three times a week, as were the sedimentation rate and the level of salicylate in the blood. All studies were carried out only once a week on the 54 controls.

In the course of the study of the 105 patients it was observed that some of the subjects were not taking the medicaments properly in spite of strict supervision. This fact was easily determined by observing the blood salicylate levels of these patients. In another study in which the primary purpose was to determine the effect of the administration of sodium bicarbonate on the level of salicylates in the blood the prothrombin time was watched closely. In this group of 9 patients supervision of medication was extremely strict and all 9 patients received the prescribed medications. They were given 150 grains (10 Gm.) of sodium salicylate daily for three weeks either with or without sodium bicarbonate. The Quick prothrombin time and blood salicylate level were determined daily except on Sundays on these 9 patients. The results on this group will be mentioned in connection with the results of the study of prothrombin content of the blood.

In order to correlate our results with the recent work of others we reviewed the literature on the various points we were studying and have compared the pertinent observations of others with our observations.

COMPARISON OF RESULTS OF OUR STUDY WITH DATA FROM LITERATURE

Prothrombins.—In February 1943 Link and his associates [7] at the University of Wisconsin reported in their continued studies on hemorrhagic sweet clover disease that the quantitative chemical degradation product of dicumarol was salicylic acid.[8] This finding prompted these workers to study the effect of salicylates on the prothrombin level of the blood in rats. They found that a single dose of salicylic acid induced a temporary hypoprothrombinemia in rats when the rats were maintained on a ration low in vitamin K. This phenomenon did not occur when the rats were on a diet containing sufficient vitamin K. Furthermore, menadione protected the rat against the hypoprothrombinemic producing action of salicylic acid. It was observed that a dose of 25 mg. of sodium salicylate administered intravenously to rats on a diet deficient in vitamin K increased the prothrombin time of diluted plasma (12.5 per cent) from a normal of 39 to 72 seconds. In addition, it was found that on the low vitamin K ration rats receiving 100 mg. of salicylic acid daily developed severe hypoprothrombinemia in twenty days. Rats on the artificial ration, which was extremely low in vitamin K, developed a temporary mild hypoprothrombinemia even after single oral doses of 10, 25 or 100 mg. of salicylic acid.

Shortly after this report, two studies appeared which indicated that salicylates administered to man had an effect on the prothrombin level similar to that observed originally by Link and his associates in rats. Meyer and Howard reported that the prothrombin level of most of 13 subjects who received 80 grains (5.3 Gm.) of acetylsalicylic acid daily for periods of three to eleven days was reduced to about 50 per cent of normal, and in addition the coagulation time increased from an average control level of 18 to 25 minutes. These authors usually noted an effect on the prothrombin level the day after the first administration of the drug, but in most instances the maximal effects were not observed until the drug had been administered for three or four days or more. When administration of the drug was discontinued, the prothrombin level and coagulability of the blood usually returned to normal in from two to four days. From 75 to 80 grains (5 to 5.3 Gm.) of sodium salicylate was administered to 6 patients in divided doses for periods of seven to eight days and 40 grains (2.6 Gm.) in divided doses to three others for periods ranging from three to eight days. The effects on the prothrombin and coagulation time were similar in all respects to those of acetylsalicylic acid. It was noted further that the administration of menadione would protect the persons receiving salicylates from hypoprothrombinemia. Similar observations were made by Shapiro also, who reported that from his clinical studies approximately 1 mg. of synthetic vitamin K would counteract the prothrombinemic inducing action of 1 Gm. of acetylsalicylic acid.

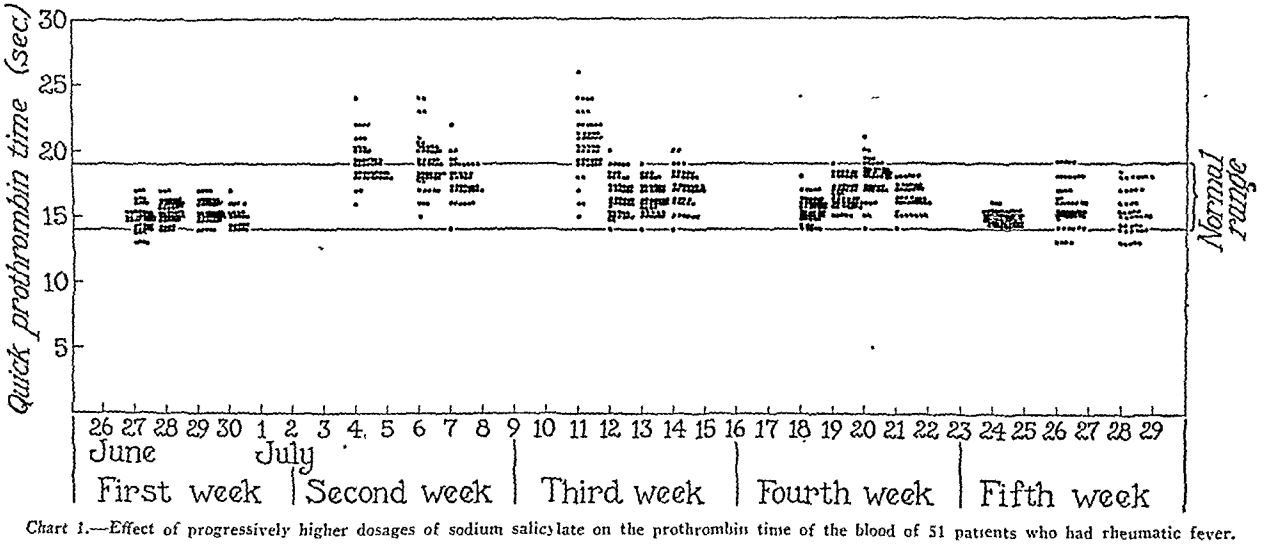

Chart 1.—Effect of progressively higher dosages of sodium salicylate on the prothrombin time of the blood of 51 patients who had rheumatic fever.

Since the appearance of these two clinical studies, several editorials have pointed out that the administration of salicylates might not only be a factor in production of hemorrhagic manifestations among patients with rheumatic fever who are receiving salicylates but also might account for some of the unexplained hemorrhages that occur in acetylsalicylic acid addicts.

In chart 1 is demonstrated graphically the effect of the administration of sodium salicylate over a long period on the prothrombin content of the blood of the 51 patients. It will be observed that during the first week when the daily dosage was 50 grains (3.2 Gm.) of sodium salicylate there was no change in the prothrombin time from normal levels. In the second week, however, two days after the dosage had been increased to 100 grains (6.6 Gm.) the prothrombin time began to increase. It was not, however, until the patients had been receiving 150 grains (10 Gm.) of sodium salicylate daily for two days that a good percentage of them had an elevation in the prothrombin time. Even with increased salicylate dosage the prothrombin time did not increase beyond the initial increase or remain high in all cases. This phenomenon is difficult to explain but tends to support the original observation

7. Link, K. P.; Overman, R. S.; Sullivan, W. R.; Huebner, C. F., and Scheel, L. D.: Studies on the Hemorrhagic Sweet Clover Disease: XI. Hypoprothrombinemia in the Rat Induced by Salicylic Acid, J. Biol. Chem. **147**: 463-474 (Feb.) 1943.

8. A side observation in our present study is pertinent; namely, that salicylate could not be detected in the blood of a patient who had great prolongation of the Quick prothrombin time following the ingestion of dicumarol.

by Link and his associates [7] that the prothrombin time in rats is affected little by increase in dosage of salicylic acid from 10 to 100 mg. It is difficult to compare our results with previous reports primarily because our studies have been carried out over a much longer period and the dosages employed have been increasingly larger. At no time during this study were any abnormal hemorrhagic manifestations noted in the 51 patients taking salicylates.

In chart 2 are represented graphically the weekly prothrombin determinations on the controls. This group showed no appreciable change in their prothrombin time over the period of four weeks during which they received sodium bicarbonate.

In chart 3 are represented graphically the prothrombin determinations for 9 patients who received 150 grains (10 Gm.) of sodium salicylate daily with or without sodium bicarbonate over a period of three weeks. As previously noted by other investigators, the prothrombin time did not rise until about the second or third day. The salicylate level in the blood of all these patients was between 30 and 50 mg. per hundred cubic centimeters throughout the study. In spite of this high level of salicylates in the blood there was no great progressive increase in the number of patients who had an abnormal prothrombin time. Even on this therapeutic dosage of salicylates the increase of prothrombin time was not pronounced, and at no time in any case was any hemorrhagic manifestation noted.

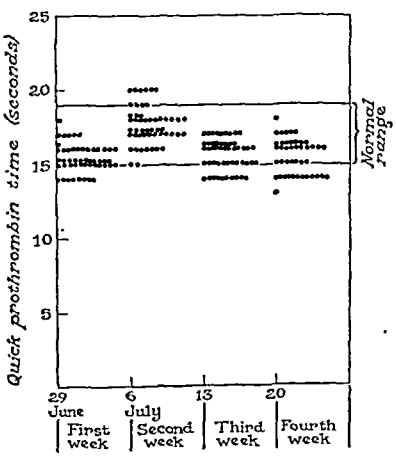

Chart 2.—Effect of progressively higher dosages of sodium bicarbonate on the prothrombin time of the blood of 54 patients who had rheumatic fever and were serving as controls for this study.

Hepatic Parenchyma.—Hanzlik and Wetzel [9] have reported that salicyl is not chemically changed by the liver. They reported that in dogs with hepatic degeneration from phosphorus poisoning the urinary secretion of salicyl was as prompt and as good as in normal control dogs. Smyth and Whipple [10] found no effect from sodium salicylate, in therapeutic doses, on the excretion of bile salts in dogs with permanent biliary fistulas. In the present studies the van den Bergh reaction was indirect for all patients in both groups before, during and after the study. Likewise the serum bilirubin was not increased above normal in any instance nor was the hepatic function altered as measured by the dye retention method. It is realized that there are many more sensitive tests of liver function which might have detected some minor degree of hepatic parenchymal damage in these cases. However, the interpretation of such minor alterations in liver function is indeed difficult. It is our impression from this study that sodium salicylate, even in large doses, has little, if any, deleterious effect on the hepatic parenchyma.

Levels of Salicylate in the Blood.—Only for a short period have satisfactory methods been available which could measure the salicylate level in the blood of man. Although the salicylate level was determined three times a week for five weeks on the 51 patients who were taking salicylates, these results are not shown for several reasons. It was noted in this study that even in the third and fourth weeks of medication there were instances in which the salicylate level of the blood was still less than 20 mg. per hundred cubic centimeters. It was difficult to believe that any of these patients with such low levels possessed any abnormality in regard to absorption of the drug. In light of some of our more recent studies on absorption, the only explanation is that these subjects in some manner did not take the salicylates which were ordered for them. In fact, some later admitted that this was the truth. Such an unfortunate circumstance is nearly unpreventable in a large military institution and parallels closely the experience of medical officers attempting to maintain adequate prophylaxis with atabrine in troops in the South Pacific area and of those trying to give prophylactic dosages of sulfadiazine.

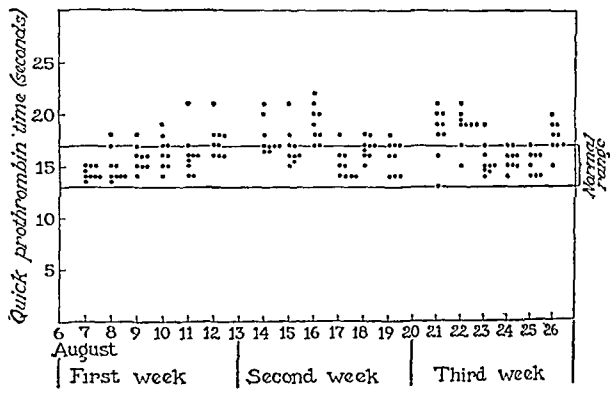

Chart 3.—Effect of the [illegible] grains (10 Gm.) of sodium salicylate with and [illegible] on the prothrombin time of 9 patients who had [illegible] level of salicylates in the blood of all these [illegible] 0 mg. per hundred cubic centimeters.

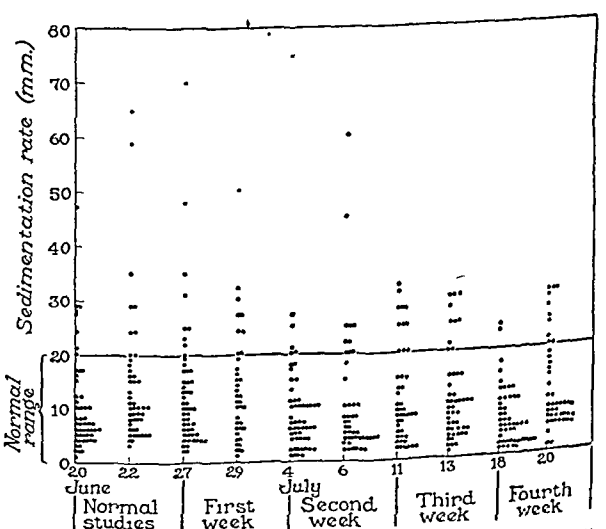

Chart 4.—The normal and triweekly blood sedimentation rates of 51 patients with rheumatic fever who were taking sodium salicylate in increasing amounts.

A large majority of the patients, however, took the drugs as ordered and the blood salicylate level of all

of these when they received 150 grains (10 Gm.) of sodium salicylate a day varied between 30 and 50 mg. per hundred cubic centimeters. After medication was discontinued, the blood salicylate level fell rapidly and was nearly zero at the end of three or four days. From this study it would seem that adequate level of salicylate in the blood is maintained in most persons on an oral dosage of 100 to 150 grains (6.6 to 10 Gm.) of sodium salicylate daily.

Sedimentation Rate.—The effect of administration of salicylates on the sedimentation rate has been a subject of considerable controversy for many years. Some students believe that the administration of salicylates in most instances is followed by a fall in the sedimentation rate. Others feel that the fall in the sedimentation rate is at least speeded by the administration of this drug. Many others, however, are equally convinced that the administration of salicylates has little effect on the alterations, up or down, of the blood sedimentation rate in rheumatic fever. Charts 4 and 5 represent graphically the sedimentation rates for

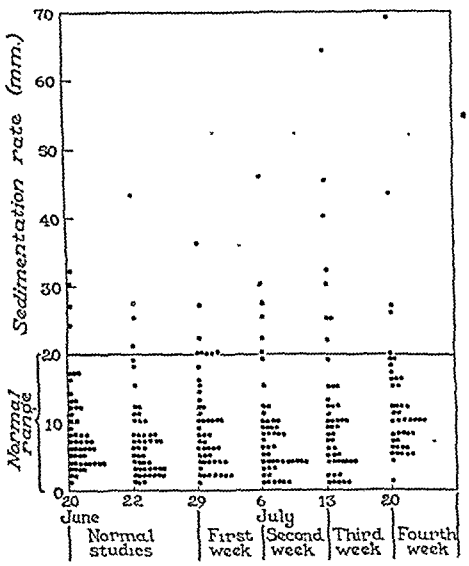

Chart 5.—The normal and weekly blood sedimentation rate of 54 patients with rheumatic fever serving as controls. These patients were receiving sodium bicarbonate in increasing amounts.

both groups of patients studied. It will be observed in chart 4 that in spite of continuous administration of salicylate a few patients, as mentioned before, had recurrence of acute polycyclic rheumatic fever with a subsequent rise in the blood sedimentation rate. Most of these men had an adequate salicylate level in the blood. In spite of the continued high dosage of salicylates, the sedimentation rate remained elevated in a few of these patients throughout the study. The controls, however, had nearly the same number of rises in the blood sedimentation rate as the patients treated with sodium salicylate; in most instances these too represented a recurrence of rheumatic fever.

It has been shown by Coburn [11] and others that the administration of large doses of salicylates in a first acute attack of rheumatic fever is followed by a rather rapid fall in the blood sedimentation rate. The present studies suggest that patients with polycyclic rheumatic fever do not respond clinically, nor does the sedimentation rate respond to the administration of salicylates in a manner comparable to that observed in a first acute attack. At present there is no known explanation for this interesting phenomenon.

Urine.—Hanzlik [12] reported that the administration of sodium salicylate in full therapeutic doses invariably causes the appearance of albumin, leukocytes and granular casts or castlike bodies in the urine of normal, rheumatic, convalescent, febrile and afebrile persons. They observed that quantitatively the albuminuria reached its maximum at the time of symptoms of salicylism and then gradually diminished and eventually disappeared. They further noted that the administration of sodium bicarbonate in amounts equal to the dosage of salicylates had no effect on the albuminuria. Our findings are nearly exactly opposite to those reported by Hanzlik. A few leukocytes were found in specimens of urine from only 6 of the 51 patients who received large doses of sodium salicylate. In each of these 6 cases the leukocytes were found in only one specimen of urine. Similar observations were made on 8 of the controls. In neither group of patients was albuminuria noted on any occasion.

Blood.—In charting the effect of salicylates and sodium bicarbonate on the hemoglobin and erythrocyte count, it is our impression that both the hemoglobin level and the erythrocyte count decreased slightly. This, however, may result from the disease rather than from the drug. The leukocyte count was unaffected in either subjects or controls.

COMMENT

This study confirms previous reports that the administration of sodium salicylate results in some effect on prothrombin content of the blood. This study made with undiluted plasma shows, however, that this effect is not great and that with even large dosage the prothrombin content of the blood is not dangerously reduced and hemorrhage from therapeutic administration of salicylates is certainly unlikely. Many instances have been recorded in the literature [13] in which administration of salicylates in fatal doses has been followed by hemorrhagic changes as noted at necropsy. Purpura, however, occurs in many cases of rheumatic fever in which the prothrombin time is normal and salicylates are not being given. To assume that such objective findings in cases of rheumatic fever are a result of salicylate therapy is misleading. On the other hand, if any surgical procedure is contemplated or arises as an emergency in case of rheumatic fever in which large doses of salicylates are being administered, vitamin K obviously should be given before and after operation.

As with dicumarol, the increase in prothrombin time following administration of salicylates is not noted until twenty-four to thirty-six hours after administration of the drug. There seems to be little correlation between the increase in prothrombin time and the level of salicylates in the blood. In other words, when once the rise in the prothrombin time has taken place, an increased dosage of salicylate seems to have no tendency to cause a further increase in the prothrombin time.

The question arises as to why patients taking salicylates do not all have an increase in the prothrombin time. The work of Link and his associates indicates that the level of vitamin K in the diet has a profound influence on the hypoprothrombinemic action of salicyl-

ates in rats. The difference in the intake of vitamin K might explain why only certain ones of our patients developed hypoprothrombinemia following administration of salicylates. It also would be interesting to know whether prothrombin A or prothrombin B is affected by administration of salicylates.

SUMMARY

From this study the following observations were made:

1. The administration of sodium salicylate with sodium bicarbonate in therapeutic doses to patients with rheumatic fever is followed by an increase in the Quick prothrombin time. In none of the cases reported were any hemorrhagic manifestations noted following the administration of salicylates.

2. Under the circumstances of this study, the administration of salicylates had no deleterious effect on the hepatic parenchyma.

3. A dosage of 150 grains (10 Gm.) of sodium salicylate daily is followed in most instances by a blood level of salicylate of 30 to 50 mg. per hundred cubic centimeters. When the level of salicylates in the blood falls much below these figures, one can suspect that the patient is not taking the drug.

4. In recurrent attacks of polycyclic rheumatic fever the sedimentation rate is little affected by the administration of salicylates.

5. Long continued high dosage of salicylates is followed by a slight reduction in the hemoglobin content and erythrocyte count. The leukocyte count is unaffected by salicylates, as is the urine.

STATISTICAL STUDY OF 265 CASES OF HEAT DISEASE

COLONEL DANIEL L. BORDEN
LIEUTENANT COLONEL JAMES F. WADDILL
AND
CAPTAIN GEORGE S. GRIER III
MEDICAL CORPS, ARMY OF THE UNITED STATES

When work involving muscular exertion is performed by the human body over a sustained period of time in an atmosphere having a high external temperature and a high humidity, the pathologic effects of heat accumulation are frequently observed. Such a condition represents a potentially serious medical problem and one which may prove rapidly fatal in its later stages. Its proper control and treatment are highly important, especially when a large number of individuals are concerned.

This problem has been recognized and studied by many industrial plants and organizations over some years, and a great deal of progress has already been made in its management.

Modern warfare has focused further attention on heat exhaustion because of its high casualty rate in operations under adverse climatic conditions, especially in tropical and semitropical locations. Both the British and American armies have encountered the problem in training as well as in combat operations. In the Iraq campaign the casualty rate among British troops was higher from heat (8 per cent) than from all other causes (4.1 per cent).[1]

At this post the high incidence of heat exhaustion during the summer months has been a major medical concern. Fort Eustis is located along the southern coastline, situated on a low flat peninsula, bounded on the north and south by rivers. During the months of June, July and August there is a high external temperature with a high humidity and a low wind velocity. Troops, particularly unseasoned troops, undergoing training under such climatic conditions show a high casualty rate from the effects of heat. In the summer of 1942, 4 cases of heat stroke were admitted to the hospital in shock with pulmonary edema and terminated fatally despite heroic treatment. This experience stimulated an intensive investigation of the available data on heat disease, and the present report deals with the results of our investigation and subsequent management of the problem.

PHYSIOLOGIC CONSIDERATIONS

Man, as a warm blooded animal in contrast to a cold blooded animal, possesses certain mechanisms to maintain a constant body temperature despite the temperature of the environment. This stability of temperature represents the resultant of the balance between the mechanisms of heat production and heat loss.[2] If one of these mechanisms fails, there is a consequent gain or loss of body heat. The genesis of the condition commonly termed heat exhaustion or heat stroke usually occurs from a diminution or failure of the means of heat loss possessed by the human body.

According to Wiggers,[3] body heat is lost or dissipated by the following routes:

(*a*) Small amounts by warming the food and respired air and with the excretions (although this is not in universal agreement with all authors).

(*b*) About 15 per cent by saturation of the air in the lungs and by heat absorbed in eliminating carbon dioxide.

(*c*) The remainder (over 80 per cent) by conduction, by convection, by radiation and by vaporization of water.

The heat loss through radiation, convection and conduction depends mainly on:[4]

(*a*) Air temperature and other environmental conditions (i. e the humidity).

(*b*) The nature and amount of clothing.

(*c*) The quantity of heat produced in the body reflected by the degree of body temperature.

It is well known that the exposed skin surface acts as a black body radiator to the direct rays of the sun and thus will absorb heat rapidly from this source. The infra-red or heat waves may however be deflected by satisfactory clothing.

It is very important to evaluate properly the part played by the vaporization of water as a means of heat loss in the production of pathologic effects from heat accumulation. Below atmospheric temperatures of 28 to 30 C. (82.4 to 86 F.) vaporization of water from the skin plays little part as a means of heat dissipation[5] (about 25 per cent and a third of this is due to loss of water by respiration).[6] While the percentage of heat loss by vaporization of water is nearly constant below this level, as the external temperature rises above it and approaches 35 C. (95 F.) vaporization of water becomes an increasingly impor-

6. Wiggers,[3] p. 932.

tant means of heat dissipation until at or near 35 C. it is practically the sole means of heat loss.[7] Effective vaporization of water from the skin surface depends chiefly on the ability of the surrounding air to absorb additional moisture (i. e. the degree of relative humidity) and to some extent by movement of the surrounding air.

Another important feature of effective heat dissipation under adverse weather conditions is that the relative humidity of the air has little effect on heat loss by convection; probably the most important factor influencing heat loss by this means is air movement (wind velocity).[5] This is of some importance in properly correlating the wind velocity with other meteorologic data in relation to possible or probable incidence of heat disease over any given period.

From the foregoing discussion it would seem that the relative humidity would be the most important meteorologic reading in considering atmospheric conditions likely to produce heat effects. This is not totally true. The relative humidity per se does not seem to be the critical factor. On two days, June 8 (fig. 1) and July 8 (fig. 2) the relative humidity was high (86 and 85), but also comparatively low dry bulb and wet bulb temperatures were existent with a low wind velocity. No heat cases occurred. Conversely, on June 2 and 3 (fig. 1) the relative humidity was low (43 and 41 respectively) but the dry and wet bulb temperatures were high, with a wind velocity of approximately 10 miles per hour. The incidence of heat cases was high, especially on June 2.

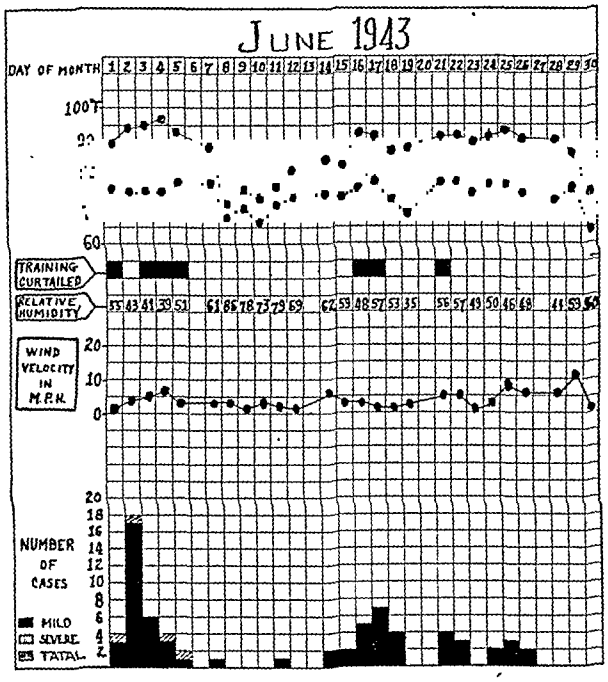

Fig. 1.—Highest daily dry temperature with corresponding wet bulb temperature, relative humidity, wind velocity and number of and severity of cases each day during June 1943. In figures 1, 2 and 3 the upper (solid line) temperature curve is dry bulb and the lower (broken line) is wet bulb.

On the other hand, the wet bulb temperature seems to be a good indicator of the probable incidence of heat disease. The possible explanation for this is that the wet bulb temperature is the resultant of two factors: the external temperature and the degree of saturation of the air with water vapor (humidity). At temperatures of 28 to 30 C. (82.4 to 86 F.) and below, the mechanisms of convection, radiation and conduction play a large part in total heat loss, sufficient to compensate for little loss by vaporization of water. At temperatures of over 30 C. (86 F.) vaporization of water plays an increasingly predominant role, but even a comparatively low relative humidity of the atmosphere is not a sufficient compensation to prevent heat accumulation with high wet and dry bulb readings, if the wind velocity is low.

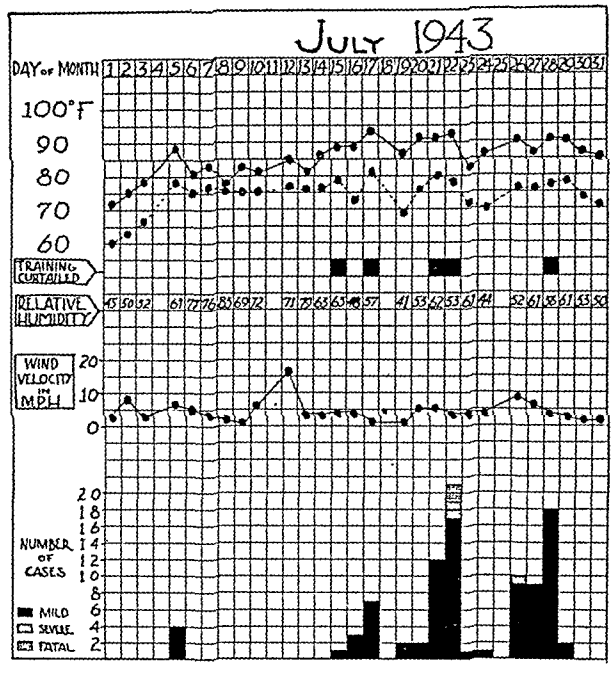

Fig. 2.—Highest daily dry temperature with corresponding wet bulb temperature, relative humidity, wind velocity and number and severity of cases each day during July 1943.

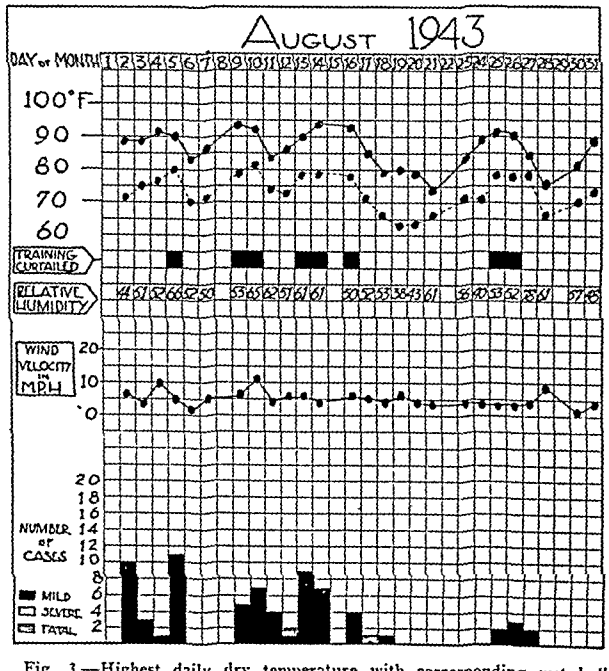

Fig. 3.—Highest daily dry temperature with corresponding wet bulb temperature, relative humidity, wind velocity and number and severity of cases each day during August 1943.

7. Wiggers,[2] p. 933, figure 205.

Figures 1, 2 and 3 show clearly the effect of physical exertion on the incidence of heat disorder. No heat cases were seen on any Sunday during the three month period illustrated, a day on which physical training, activity and exposure to direct rays of the sun were at a minimum.

INCIDENCE AND SYMPTOMATOLOGY

The pathologic manifestations of the effects of heat accumulation in the body are generally grouped under the general term of heat disease.

This is divided into:

Heat cramps (muscle cramps from salt loss).[8] (This is, however, not entirely specific for heat cases alone, as it may occur in any environment as a result of salt and fluid loss.)

Heat prostration,[9] characterized by weakness, usually some temperature elevation, anorexia, headache, abdominal distress, nausea, vomiting and visual disturbances.

Heat exhaustion, when evidence of circulatory failure is present in addition to the effects of heat accumulation. High temperature may or may not be present, depending on the degree of shock present.

Heat stroke, representing a failure of the heat regulatory mechanisms with hyperpyrexia as the predominant feature; coma may or may not be present.[9]

The onset of heat distress may be gradual and insidious and elicit only casual attention, but an abrupt rapid change into one of the more serious forms is not uncommon.

The accompanying table shows the statistical data on the incidence, symptomatology and effects of physical training on heat disease based on our observation of 265 cases from May 1 through September 1943.

Statistical Study of 265 Cases of Heat Disease

May–September 1943

Geographic Location of Cases:		
Home states		
Southern		15.8%
Northern		81.5
Stay in hospital:		
3 days or less		88.0%
Training activity:		
Patients in first 4 weeks of training		39.0%
Patients in 5-8 weeks of training		38.0
Patients past 8 weeks of training		23.0
Age limit (18-39 years):		
Patients 18-21 years of age		53.0%
Patients 22-30 years of age		25.0
Patients over 30 years of age		22.0
Symptomatology:	Mild Cases	Severe Cases
Nausea	18.0%	13.0%
Vomiting	5.0	13.0
Vertigo	74.0	88.0
Headache	19.0	53.0
Muscle cramps	14.0	13.0
	8.0	0.0
	48.0	100.0
	31.0	37.0
Cyanosis	5.0	50.0
Tachycardia	40.0	100.0
Fever (over 99.6 F.)	78.0	100.0
Systolic blood pressure under 100 mm. of Hg.	4.0	75.0
Comatose	0.0	84.0
Treatment:		
Oxygen (100%) inhalation	48.0	100 0
Isotonic solution of sodium chloride (intravenous)	27.0	25 0
Plasma	12.0	88 0
Sedation (mild)	28.0	75.0

The striking difference shown in the incidence of heat disease between men of the Northern and Southern sections of the country is probably more apparent than real, because comparative figures for the entire population of the post showing the number of men from various geographic localities were not compiled.

For the five month period of May through September 1943 there was a total of 265 cases of heat disease seen at the station hospital: 23 in May, 70 in June, 92 in July, 72 in August and 7 in September.

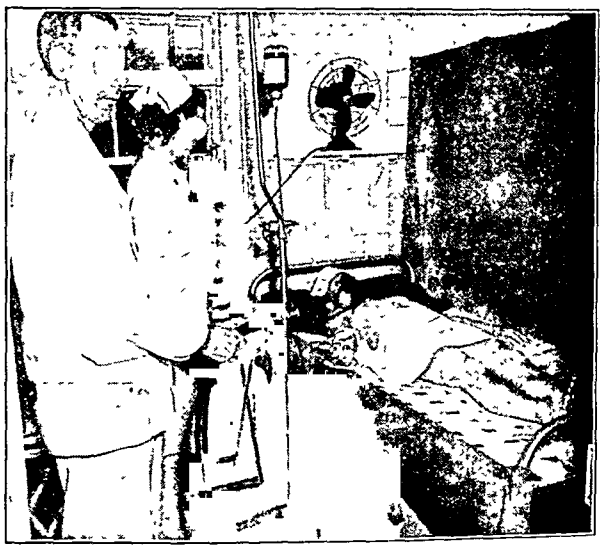

Fig. 4.—Equipment for the treatment of heat disease. Fan under lattice bed is not shown.

TREATMENT

Initial experiences based on our own series of cases revealed that the rapidity with which treatment was begun after the diagnosis was made exerted a major influence on the prognosis of the case. This is especially true in the more severe forms of the disorder. For this reason a special treatment room, especially equipped and staffed by trained personnel, was set up in one of our wards (shown in figure 4). A patient suffering from heat disease is regarded as a medical emergency, and his prompt arrival in the ward is expedited by every possible means. Any intermediary treatment or examination in the hospital or field is discouraged.

For purposes of therapy, cases were divided into two general classes: (1) those without shock or circulatory failure (heat prostration; muscle cramps or spasm due to salt depletion); (2) those with circulatory failure or shock present or impending (heat exhaustion; heat stroke). The latter two classes of heat disease were regarded as severe forms of the same pathologic process but of different degree; the former predominated by the picture of circulatory collapse, while the latter appears largely as a severe metabolic change characterized chiefly by hyperthermia. The circulatory changes observed in heat exhaustion have been compared to those noted in mild adrenal cortical insufficiency.[10]

In the milder cases of group 1 generally complaining only of weakness, headache, nausea and malaise, sedation is promptly given (bromides, phenobarbital or sodium amytal by rectum or hypodermically to avoid nausea); an ice cap is placed on the head; a tap water sponge bath is given; increased ventilation over the exposed surface of the body is secured with electric fans; an increased intake of fluids and salt in the form of salinized water (0.1 per cent) cooled to 50 degrees is forced orally. If nausea and vomiting were present,

8. Talbott, J. H.: Water and Salt Requirements in Health and Disease, J. A. M. A. **119**: 1418 (Aug. 22) 1942.
9. Wiggers,[3] p. 941.
10. Duncan, Garfield, G.: Diseases of Metabolism, ed. 1, Philadelphia, W. B. Saunders Company, 1935, p. 268.

1,000 cc. of 0.9 per cent sterile saline solution was given slowly by the intravenous route or by hypodermoclysis, depending on the individual indications of the particular case. The intravenous administration of 0.9 per cent saline solution seemed specific for relief of muscle (heat) cramps.

The temperature, pulse, respiration and blood pressure were checked at hourly or half-hourly intervals, depending on the exigencies of the case, until a stable, normal level was reached.

If the rectal temperature is over 102 F. the skin surface of the trunk and extremities is sprayed at five minute intervals with a fine mist tap water spray delivered from any suitable spray equipment, and increased evaporation of this is effected by directed air currents from electric fans. When the rectal temperature reaches 102 F. or is initially below this reading, the fan-spray is not advised, as too rapid cooling of the body may be subsequently produced. While the spray is in use, the temperature is checked every fifteen minutes.

In the treatment of the more severe cases in the second group (heat exhaustion, heat stroke) in which shock may be present, the rapid restoration of the circulating fluid volume is perhaps the chief objective to be accomplished. In heat stroke rapid cooling of the body is the main objective of therapy. In addition to the general principles of therapy already discussed additional procedures are used:

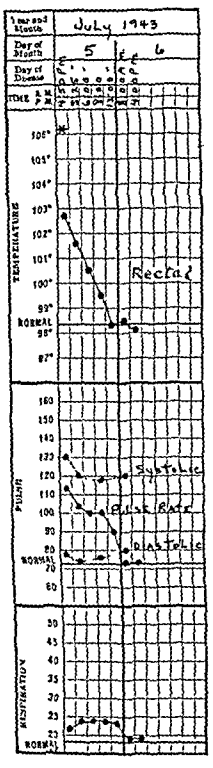

Figure 5

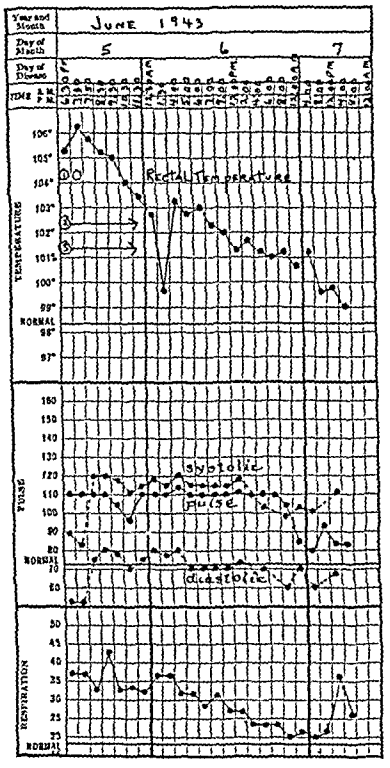

Figure 6

Fig. 5 (F. B., white man).—Clinical course of a mild case of heat disease following treatment. Treatment (*) 1,000 cc. of isotonic solution of sodium chloride intravenously and tepid sponge.

Fig. 6 (L. A., white man).—Clinical course of a severe case of heat disease following treatment. Treatment: (1) 500 cc. of blood plasma, (2) body surface kept wet with fine tap water spray, (3) 100 per cent oxygen by B. L. B. mask.

1. Five hundred cc. of plasma by vein is given immediately and repeated in thirty to forty-five minutes if the blood pressure response has not been satisfactory. The use of intravenous salt solution for this purpose has not seemed advisable to us owing to its ready diffusibility into the tissues through dilated and possibly damaged capillary walls. In addition, it is felt that this characteristic might aid in precipitating a pulmonary edema. Depletion of plasma and tissue chlorides[10] from excess sweating and fluid loss may be restored on recovery from shock.

2. One hundred per cent oxygen is administered by mask to combat the reduced oxygen carrying capacity of the hemoglobin, which is stated by Wiggers[11] to be reduced in this condition and the tissue oxygen deficit due to circulatory deficiency.

3. The extremities are massaged to stimulate circulation through these parts.[12]

4. Circulatory stimulants such as ephedrine, caffeine, amphetamine or metrazol are used as additional aids in restoring an adequate circulation, if needed.

Figure 5 shows the response to treatment in a mild case (group 1, no plasma or oxygen therapy given); intravenous saline solution was given on admission. Figure 6 reveals the response in a more severe case to treatment (group 2, plasma and oxygen given). The prompt response of the blood pressure to plasma can be seen.

During the five month period of 1943 three fatalities occurred, a mortality rate of 1.1 per cent. Although no figures for comparison of therapeutic results by different methods of treatment are available to us, this routine has seemed a satisfactory method of approach on the basis of our results.

PATHOLOGIC FINDINGS

A detailed description of the pathologic findings will not be given in this paper, as these are to be the subject of a separate report from the Pathology Department. The final pathologic diagnoses based on postmortem examinations in 3 fatal cases in 1943, however, will suffice to show the common findings and their similarity:

(*a*) Subendocardial hemorrhages of the interventricular septum near the base of the aortic and pulmonic vessels and adjacent areas of the papillary muscle, with involvement of the conduction system. (All 3 cases showed these findings.)

(*b*) Petechial hemorrhages involving scattered areas of (1) the cerebrum, (2) the duodenal mucosa, first and second portions, (3) subserous areas of the large intestine, (4) the peritoneal serosa, (5) the lungs, (6) the kidneys.

(*c*) Hemorrhages and edema of the brain involving the midbrain, hypothalamus, pons, hippocampus, meninges and periventricular region of the thalamus (1 case).

(*d*) Intra-alveolar hemorrhage of the lungs, bilateral, acute (1 case).

(*e*) Passive congestion of the liver, spleen, kidneys and lungs (3 cases).

All three fatalities occurred in men who had undergone strenuous physical exertion under adverse climatic conditions with high wet and dry bulb temperatures. One of these men was found to have died in his barracks during the night, following a day of strenuous physical activity.

Clinically, in several nonfatal cases with pronounced hyperthermia, scattered subcutaneous petechial hemorrhages over the surface of the trunk and extremities were noted. Differentiation of the more severe forms of heat disease, especially those with petechial lesions and other forms of acute pathologic change such as meningococcic infection, bacterial endocarditis, typhus

and typhoid, may at times be difficult. Blood culture, agglutination tests, examination of the skin lesions [13] plus a careful physical examination and history will at times be necessary in order to arrive at a correct diagnosis. Trauma likewise in obscure cases will have to be ruled out.

Suspension of Close Order Drill and Strenuous Training

Fig. 7.—Daily and hourly meteorologic chart maintained as a guide to the administrative control of excessive exercise.

PROPHYLACTIC CONTROL

Daily meteorologic data during the "hot season" of the year when atmospheric temperatures are high on both the wet and dry bulb thermometers are an important feature in exercising preventive control over a serious incidence of heat cases.

Our figures for critical wet bulb temperatures agree with those given in a recent British article [1] on heat effects in a tropical climate. Their findings were:

(*a*) Physical activity should be on a reduced scale at a wet bulb temperature of 75 to 76 degrees.

(*b*) At 79 degrees wet bulb all physical activity (such as long marches, drills and calisthenics) was halted for unseasoned troops.

(*c*) Seasoned troops who had been acclimated could carry on limited physical activity up to a wet bulb reading of 80 to 81 degrees.

Based on the British standards, our figures for curtailment or limitation of strenuous physical training were arbitrarily adopted. The correlation of the wind velocity with these figures was put in on an experimental basis. The limits thus in use at this post for the summer of 1943 were as follows:

(*a*) If the wind velocity is 10 miles per hour or over, the wet bulb temperature may go to 77 degrees before limiting physical activity if the dry bulb temperature does not exceed 88 F.

(*b*) With a wind velocity below 5 miles per hour (decreased means of heat loss by convection), if the wet bulb temperature reaches 75 to 76 degrees a dry bulb temperature of 88 F. is considered maximum for continuation of full physical activity.

(*c*) A wet bulb temperature of 78 to 79 degrees with a wind velocity below 10 miles per hour is considered to be the danger point for any physical activity if the dry bulb temperature is 88 F. or above.

Other important measures of preventive control are:

The intake of salt and fluid should be adequate. The use of 0.1 per cent salinized water for drinking purposes has been found by us to be the most practical means of securing this on a consistent basis. It has seemed to be superior to the distribution of salt tablets for consumption. It is palatable and well borne. The equivalent of 2 tumblers (500 cc.) is advised for consumption every sixty to ninety minutes by unseasoned troops during an exercise period on hot humid days.

The clothing should be light and well ventilated. The same type of protective head cover should be worn in direct sunlight.

The diet should be light and low in protein, especially the midday meal. It seems preferable to give the main meal in the evening after the strenuous work of the day is over.

ADMINISTRATIVE PROBLEMS

The medical administration of a military reservation located in a hot humid climate and used for conditioning trainees is a responsibility that must be recognized and met. To the post surgeon falls the duty of advising the commanding officer of the post when drills and exercise are to be curtailed or discontinued because of adverse weather conditions. To meet this responsibility scientifically it is essential that a diagrammatic hourly weather chart (fig. 7) be maintained during the summer months as a guide in curtailing the activities of troops when the heat and humidity reach a point of danger.

As shown, we have arrived at a standard of heat tolerance which is not necessarily ironclad but is subject to reasonable interpretation. A single day of heat does not receive the same serious consideration as a number of days of continuous high temperature. The longer the heat wave without respite, the more exacting the orders to curtail activity.

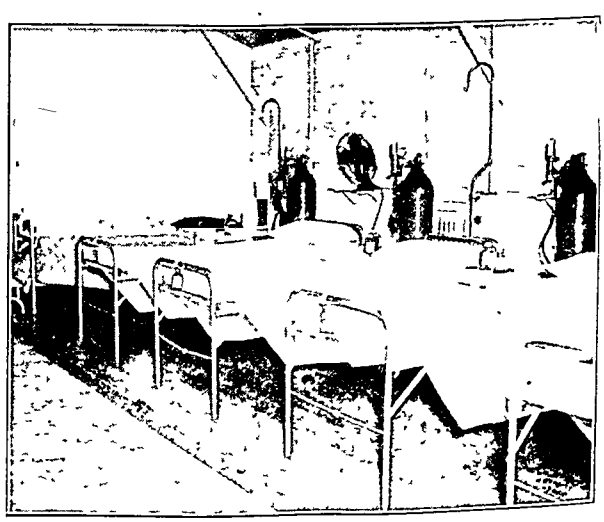

Fig. 8.—Air conditioned ward set up for immediate use. Bed in corner of room is the same equipment as that shown in figure 4. Remaining beds are set up for treatment of mild cases.

It was found that the most careful check-up system had to be employed to enforce the intake of salinized water as a preventive measure. All patients with heat exhaustion entering the hospital without a history of

13. Tompkins, V. N.: The Diagnostic Value of Smears from Purpuric Lesions of the Skin in Meningococcic Disease, J. A. M. A. 123:31 (Sept. 4) 1943.

taking the prescribed sodium chloride have been reported to headquarters for appropriate disciplinary action against the supervising officer for this oversight. This has brought results.

Instructor officers, trained in the Southwest section of our country (Texas), where the temperature is high, the atmosphere dry and the nights cold, have used woolen shirts to good advantage for the protection of their men on hikes and drills. The blast effect of stoking a furnace when the door is suddenly opened is not unlike the conditions met in heat with a dry atmosphere, where wool will ward off the rays of the sun that would otherwise penetrate cotton. This principle does not apply to high temperature with high humidity, where aeration is essential to the evaporization of moisture. This difference must at times be clarified.

Recently there have been stationed at this post British colonial troops wearing shorts with elbow length sleeve shirts. This uniform is military in appearance and the envy of our troops who are clothed in the conventional regulation long trousers and long sleeved shirts.

About eighteen months ago station hospitals were authorized one air conditioned postoperative recovery ward. Because of the urgent need at this hospital for the treatment of many cases of heat disease, this authorization was diverted to our heat project (fig. 8).

Pressure by military training centers not to curtail or cancel the activities of their prearranged program for reasons of excessive heat is not uncommon, since military instructors are limited in the time allotted to them for training. Night maneuvers constitute one way to regain lost time given up during the hot, humid daylight hours. As a safety factor, the control of this situation must be met by the post surgeon with diplomatic but unrelenting firmness.

SUMMARY

1. In a climate with a high atmospheric temperature, high humidity and a low wind velocity the incidence of pathologic effects from heat on the human body tend to be high.

2. The initial effects of heat accumulation in human beings may be mild and of insidious onset, eliciting only casual attention in its early stages. Such a condition, however, may abruptly and rapidly change into one of the more severe stages of the disorder accompanied by a high fatality rate.

3. Heat loss in man is chiefly accomplished by radiation, convection, conduction and vaporization of water.

4. As the external temperature rises above 30 C. (86 F.) vaporization of water becomes the increasingly predominant means of heat loss in the human body, until at or near 35 C. (95 F.) it is practically the sole means of heat dissipation.

5. While vaporization of water from the skin surface depends mainly on the degree of saturation of the air with moisture (relative humidity), the wet bulb temperature seems a more sensitive indicator of the probable incidence of heat disease at high atmospheric temperatures than the relative humidity per se.

6. Strenuous physical activity under adverse climatic conditions strongly increases the incidence of heat effects, especially when performed by persons not acclimatized.

7. In the treatment of the more severe cases in which circulatory failure or shock was present or impending, the intravenous administration of 1 to 2 units of plasma is recommended over the use of saline solution, owing to the ready diffusibility of the latter into the tissues. This characteristic of the latter solution presents certain disadvantages on this basis in a state of shock.

8. The use of 100 per cent oxygen by mask has proved advantageous in the treatment of shock in combating both a reduced oxygen carrying capacity of the hemoglobin and the tissue oxygen deficit.

EMERGENCIES IN THE ALLERGIST'S PRACTICE

GEORGE L. WALDBOTT, M.D.
DETROIT

Any one who treats a large number of allergic patients has had his share of emergencies. The very fact that he is dealing with hypersensitive individuals makes him more liable to accidents than other doctors. These experiences make him pause to reflect on and ponder over them, searching both for their causes and for ways of avoiding future occurrences. In the present article my own solution to this problem will be discussed, if, indeed, such a solution is possible. The subject will be presented under three headings: (A) accidents arising from skin tests, (B) accidents arising from treatment with allergenic extracts and (C) other emergencies in allergic patients.

DIAGNOSIS

Since parts 1 and 2 are concerned solely with the allergic reaction, I shall dwell briefly on its diagnosis and differential diagnosis. Regardless of whether such a reaction results from an injection of pollen extract, of animal serum, of an organic or nonorganic chemical or from inhalation or ingestion of some substance to which the patient is very sensitive, the symptomatology is very characteristic and well known. It is a combination of allergic respiratory symptoms with hives.[1] There is a tendency for the manifestation to concentrate in a preexisting shock organ; i. e., a patient with an eczema will develop considerable aggravation of the eczematous lesion, one with gastrointestinal symptoms may develop severe intestinal cramps, one with asthma may only show an attack of asthma without much accompanying urticaria, one with allergic symptoms in the uterus, uterine cramps. If the reaction is brought about by an intravenous injection, no symptoms other than collapse may be noticeable. In an individual whose allergy has been recently acquired, severe shock may overshadow all other symptoms, skin edema being completely absent. It seems as though these patients are not as yet able to react to the influx of the antigen into the system with the hives and with the usual asthmatic attack.

DIFFERENTIAL DIAGNOSIS

Confusion may arise by not clearly distinguishing these reactions from nonallergic ones which may result from any type of hypodermic medication. The following conditions should be considered in differential diagnosis:

1. *Syncope.*—The ordinary fainting spell is the most frequent source of diagnostic difficulties, especially if convulsions accompany the fainting. The low pulse rate and the relatively prompt recovery after the patient assumes a prone position permit one to make the proper diagnosis.

---

1. Waldbott, G. L.: Systemic Reactions from Pollen Injections, J. A. M. A. 96: 1848 (May 30) 1931; The Prevention of Anaphylactic Shock,

2. *Febrile Reactions.*—These appear within an hour or two after an injection. They are brought on by contamination of the injected material with bacterial and other protein elements or by certain chemicals originating from rubber ware used in preparing the solutions.

3. *Focal Reactions.*—Focal reactions from hypodermic injection of any kind represent the activation of a dormant focus of infection.[2] On several occasions I have seen the flare-up of a chronic appendicitis, a furuncle, a tooth abscess or a sinus infection from an injection of pollen extract.[3]

4. *Reactions from Pulmonary Thrombosis.*—These are very rare. If the patient develops, immediately after an injection, a severe pain in the chest, cough and expectoration, followed by a low grade bronchopneumonia, this possibility should be kept in mind.

5. *Toxic Reactions.*—These result from the action of an injected drug. Thus the vasodilating effect of an intravenous injection of aminophylline or the characteristic response to epinephrine may be confused by the inexperienced with an allergic reaction.

A. REACTIONS FROM SKIN TESTS

During intradermal skin testing, reactions are brought about by an extreme degree of sensitivity to the tested material. Among the fatal cases reported in the literature, some may have been induced by the accidental introduction of the testing material into a small vein. Since such reactions are encountered but rarely in dermal tests, some clinicians believe that they can safeguard themselves against such accidents by taking the precaution of doing preliminary dermal tests before the intradermals are done. Generalized reactions however occur in spite of negative scratch tests.[4] The most obvious reason for this is the fact that scratch testing material loses its potency relatively soon.

The following precautions may be taken to prevent accidents from intradermal testing:

Rule 1. In children below 6 years of age, skin tests should never be done by the intradermal method. The most severe reactions are, in my experience, encountered in this age group. A great deal of trouble has been avoided in my own work since the introduction of this rule. Passive transfer tests in young children are not only most reliable to the physician but are also appreciated by parents and by children alike.

Rule 2. If, in the course of history taking, a patient mentions that the ingestion or inhalation of a particular antigenic material has given rise to asthma, hives or allergic shock, a C for caution is entered on the record. Automatically these materials are excluded from intradermal testing. In other words, if a patient develops an attack of asthma or of hives on being near a horse or on eating peanuts, it can be taken for granted that he is sensitive to the horsehair or the peanuts. If a quantitative study of this sensitivity is indicated, however, such extreme dilutions (i. e. 1:1,000,000) are used for testing as to exclude the possibility of any harm. Every twenty minutes a stronger dilution is administered, intradermally, until a fairly strong wheal is obtained.

Rule 3. An attempt is made to gain a general impression of the patient's state of sensitivity by the response to the tests which are done first. Pollens are well suited to serve as a guide for such an estimate because they are the most common reactors in allergic patients, and from the history a clue can be obtained as to the strength of concentration for the intradermal tests. If the reactions to pollens are very strong, all subsequent testing is done with a diluted set (1:10) instead of with the regular testing materials. Since tests for nuts, fish and beans have brought on more frequent reactions than other antigens, they are done last. Fish and nuts are frequently omitted altogether if the wheals from the other tests are unusually extensive.

Rule 4. This concerns the technic of testing. Arms and legs are preferable to the back for the tests because a tourniquet can be applied if necessary. Superficial veins should be carefully avoided. When the wheals are seen to spread out shortly after the injections, a tourniquet and epinephrine should be kept in readiness. After the tests have been given the patient should be carefully watched, particularly within the first few minutes. Incidentally, the layout of an allergist's office should be arranged in such a manner that all the patients are in constant view of the physician or his personnel. The closing of a door after skin testing should be carefully avoided. The treatment of the allergic reaction will be discussed later.

B. REACTIONS FROM TREATMENTS

For therapeutic purposes it is necessary to differentiate clearly between a reaction from the accidental puncture of a vein and one resulting from an overdose. Such a distinction determines not only the immediate treatment but also the course of subsequent injections. A further classification is indicated, depending on whether the extract is injected directly into the blood stream or next to a punctured vein, whence it gradually seeps into the blood stream. In other words, there are three clinically distinct types of reactions, each one requiring different treatment, namely the "overdose reaction," the "intravenous reaction" and the "backseepage reaction." The incidence of these reactions was recorded in a series of 18,775 injections of pollen extract as follows:[5] backseepage reactions, 1:1,564; intravenous reactions, 1:9,387; overdose reactions, 1:308.

Intravenous and Backseepage Reactions.—The intravenous reaction is characterized by the complete absence of a local swelling at the site of injection, by its onset within ten to twenty seconds after the injection and by its unusual gravity. Internal symptoms prevail, especially those attributable to edema of the lungs and of the liver, namely, collapse and extreme bronchospasm. The full climax occurs immediately, and, with the exception of generalized weakness or a low grade pulmonary infection, little if any after effect is noticeable when it has been brought under complete control.

In contrast with this the backseepage reaction requires between one and several minutes until the first symptoms appear. A local edema, which soon becomes intense, arises at the site of injection and spreads quickly over the body surface. There may be some blood at the site of the injection or, more often, a bloody suffusion under the skin which is rapidly replaced by a wheal. The symptoms are both cutaneous and internal. They are severe, and as a rule collapse is present.

In treating the intravenous and the backseepage reaction, speed is most essential in the immediate admin-

istration of large doses (1 to 2 cc.) of epinephrine. The lapse of even a minute will alter the outcome considerably. This is followed up by aminophylline (3½ to 7 grains, or 0.2 to 0.5 Gm.), administered intravenously. The needle should be kept in the vein and, if there is no tendency to recovery within a short time, epinephrine in doses of 0.1 to 0.3 cc. may be given intravenously. This is done very cautiously by attaching to the needle a 10 cc. syringe containing some epinephrine. Blood is withdrawn and carefully mixed with the drug, and a part of this mixture is injected very slowly. If epinephrine is injected into the blood stream in full strength without this precaution, even small amounts may lead to serious brain or cardiac injuries. It is difficult to say whether or not, in these extreme emergencies, concentrated solution of glucose, administered intravenously, and oxygen, may be of assistance.

For the prevention of a reaction from venipuncture, the following precautions are suggested: 1. An effort should be made to select an area for the antigenic injection between visible veins. 2. Before injecting the extract, the plunger should be repeatedly withdrawn for evidence of blood. 3. Immediately after the injection, the site should be inspected for escaping blood. 4. Cotton should be applied with pressure on the area from which blood escapes in order to prevent backseepage. It is readily appreciated that not one of these measures is, in itself, a definite safeguard. Watching the site for superficial veins before injecting does not preclude hitting a blood vessel in the lower layers. Absence of blood in the syringe on withdrawing the plunger does not indicate that a vessel has not been punctured. One must always be aware that a single drop of extract reaching the blood stream might induce relatively severe symptoms. Furthermore, the escape of blood from the site of the injection does not necessarily indicate that a vein has been punctured. The bleeding may be capillary or arterial in origin and, therefore, harmless. Nevertheless, one should remain on guard, prepared to administer epinephrine when blood is seen. Some have advocated combining small doses of epinephrine with the antigenic extract for prophylactic purposes.[6] I consider this practical only if the treatment is given by a nurse in the doctor's absence or when dealing with exceptionally sensitive patients. Incidentally, the self administration of extracts by patients is dangerous, since, on puncturing a vein, the patient would be unable to administer the necessary further treatment.

Overdose Reactions.—The reaction from an overdose is always initiated by a local edema at the site of the treatment. This has a tendency to spread and to become more or less itchy. It can often be seen expanding along the lymph channels before generalized urticaria and respiratory symptoms occur. No matter how large the overdose may have been, there is always a lapse of time of between a few minutes up to an hour before generalized symptoms arise. The shorter this time interval, the more severe the reaction is likely to be. After the initial control by epinephrine there is a tendency to recurring urticaria. This is in contrast with the immediate onset and the immediate climax in an intravenous reaction.

The overdose may be due to error in judgment concerning the patient's state of sensitivity. It may also be brought about by switching from an old extract to a fresh and more potent one. Occasionally the simultaneous absorption of other antigens to which the patient is sensitive accounts for the effect of an overdose. If a patient has inhaled or eaten an antigen to which he is sensitive shortly before his treatment, an otherwise adequate dose may result in an overdose reaction. Such an accumulative effect from inhaled and injected antigens is encountered when, on days of high pollen or fungus concentration in the air, reactions occur like an epidemic if the doses are not properly reduced.

For the prevention of overdose reactions the following points should be stressed: careful labeling of the various concentrations of extracts; clearly displaying the labels of the bottles in the racks; employing syringes of different color for the low and the highly concentrated extracts; thorough cleansing of the syringes before they are sterilized; careful gaging of the patient's state of sensitivity by initial tests; adequate reduction of the doses with fresh extracts, particularly after a previous overdose reaction has occurred.

As to treatment, the overdose reaction, unlike the intravenous one, does not require more than 0.1 to 0.2 cc. of epinephrine unless it is unusually severe. These small doses may have to be repeated if the symptoms do not subside. Larger amounts of epinephrine produce more discomfort to the patient than the reaction itself. The application of a tourniquet above the site of injection is of considerable value,[7] which is not true in an intravenous reaction. Aminophylline may be given intravenously if indicated for asthmatic wheezing. Careful inspection of the patient's arm within ten to fifteen minutes after the injection will serve as a warning of an impending reaction. The patient should not be permitted to leave the office until the injected area has been inspected.

C. OTHER EMERGENCIES

Fortunately emergencies other than those occurring during antigenic treatment and skin testing are not frequently encountered. Shock from ingestion of food to which the patient is very sensitive, or from inhalation of certain air borne antigens, exhibits the same manifestations as the allergic reaction from an injection and has to be dealt with accordingly. In shock from ingestion, plain water enemas and the induction of vomiting are helpful. In shock from inhalation, local applications of epinephrine to the nose and a nose spray with epinephrine 1:100 may be of assistance. The system tends to rid itself of the antigen by vomiting, diarrhea or a profuse flow of fluid from the nose, lungs and sinuses, which process should be encouraged by treatment.

An asthmatic attack may be so severe that it cannot be clearly distinguished clinically from allergic shock. The most frequent cause of such extreme attacks is the ingestion of an aspirin tablet. It would lead too far afield to present detailed treatment for this condition here. Of the many therapeutic measures recommended, the only reliable means for instantaneous relief are aminophylline and epinephrine; the value of glucose, oxygen, helium and other substances is debatable. If an extreme seizure of asthma fails to respond, a bronchoscope should be introduced into the lungs for aspiration and lavage of accumulated mucus. As a life-saving procedure, this is as startling in its results as tracheotomy in diphtheria.

Few have had an opportunity to witness edema of the glottis. This may occur in the course of urticaria, in allergic shock and in serum sickness. I have recently

6. Duke, W. W.: New Method of Administering Pollen Extract for Purposes of Preventing Reactions, J. A. M. A. 94: 767 (March 15) 1930.

7. Insley, S. W.: The Control of Immediate Shock Following Hypodermic Medication, J. A. M. A. 94: 765 (March 15) 1930.

seen a child who had recurrent laryngeal stridor and evidence of glottis edema, which responded promptly to small doses of epinephrine. The patient's father had died from the same condition. Skin tests done by the passive transfer method were negative. It could not be ascertained whether or not the patient's situation was psychogenic in origin. As the only prophylaxis which one might offer, these patients should be advised to carry with them epinephrine both for inhalation and for injection. Tracheotomy might be indicated if other measures have failed.

Another rare type of accident, to which little reference is made in the literature on allergy, is seen during extreme cyanosis in the course of an asthmatic attack. The patient usually jumps forward and falls on the floor, being completely unconscious for a period of from twenty to fifty seconds. He recuperates promptly and spontaneously. I have seen this in 3 patients in my office, and others have described this condition to me. It is evidently due to anoxemia of the brain, which adjusts itself spontaneously. The fainting brings about a general relaxation of the patient, which might effect a widening of the bronchi and thus the air passes more freely into the lungs.

Emergencies have been reported from the use of drugs in allergic patients, even from such valuable ones as epinephrine and aminophylline. An individual with serious cardiac damage, who had been in the habit of administering to himself 1 cc. of epinephrine several times daily, died instantaneously on taking such a dose. Blood was found escaping from the area of injection, indicating that he might have punctured a vein. In another case an injection of epinephrine had to be made intravenously because all other attempts at reviving the patient from allergic shock had failed. Severe cerebral disturbances such as aphasia, athetotic movements and paralysis of the facial musculature developed, similar to those described recently by Applebaum.[8] This condition lasted for two days but cleared up spontaneously, and it was interpreted as the effect of the drug on the cerebral vessels. Such experiences suggest the following precautions: discouragement of self administration of epinephrine among patients; avoidance of intravenous injections; whenever possible administration of small doses only.

Intravenous injections of aminophylline have been the source of fatal reactions.[9] It is true that the peculiar sensation in the face and the mouth which is typical of its action has caused patients to faint, but in my experience, with at least 20,000 injections,[10] I have never seen any serious ill effect from it. The injection is always made very slowly. Only one third to one half of the 3¾ grain (0.24 Gm.) ampule is used, which is sufficient to procure therapeutic results. If the patient's systolic blood pressure is below 90, 0.1 cc. of epinephrine is given subcutaneously shortly before the aminophylline is injected. Incidentally, sensitivity to either aminophylline or epinephrine has never been demonstrated.

In the allergic patient emergencies may arise from any other drug. Sensitivity to acetylsalicylic acid unquestionably accounts for the most serious ones. Morphine and other opiates follow next in importance. Agents to be injected for the purpose of sclerosing varicose veins may give rise to severe allergic reactions. The development of such sensitivity to a certain drug seems to depend largely on the amount of time which has elapsed since its previous administration. If this interval is between ten days and four weeks, the patient is most likely to become sensitized. Regular daily or weekly doses appear to be less harmful. Highly concentrated glucose or salt solutions can be safely employed for sclerosing veins if one wishes to eliminate the possibility of allergic shock. In considering the proper dose of drugs, it has been suggested to us by experiments on dogs[11] that the tolerance to a certain drug is lower in an allergic individual than in a normal one.

The allergist is often consulted by the surgeon, obstetrician and dentist concerning the "best" anesthetic to use for the allergic individual. An answer to this question must necessarily be highly speculative. In 1933 I[12] reported on sensitivity to ether and pontocaine during operation. Autopsies on 2 cases of death from pantocain hydrochloride illustrated that in such emergencies a distinction should be made between sensitization to pontocaine and intoxication from the drug, each condition requiring different therapeutic measures. It is very difficult to determine whether or not a person is sensitive to a certain anesthetic, because there is no sure means of testing for it. From the point of view of sensitivity nitrous oxide anesthesia is perhaps the most harmless one. To a patient sensitive to a certain local anesthetic a spinal anesthetic may be disastrous. In 2 patients subjected to bronchoscopy under intravenous anesthesia, severe spasm of the epiglottis occurred, presumably from the anesthetic employed. The surgeon's skill in prying the larynx open with the bronchoscope prevented asphyxiation.

The following recommendations can be made to the surgeon for an operation on an allergic individual: To have epinephrine and aminophylline on hand for immediate administration, perhaps to give small doses of these drugs prophylactically, shortly before the operation; to attempt avoidance of puncturing small veins when injecting a local anesthetic by repeated withdrawal of the plunger; to refrain from the use of opiates, if at all possible, which tend to depress the respiratory center; to avoid acetylsalicylic acid scrupulously in postoperative care. In such minor surgical procedures as bronchoscopy a barbiturate given by mouth is sufficient to bring about relaxation of the patient. If a patient has to have two operations within a short time, the critical time interval during which sensitization develops should be heeded and a different type of anesthesia employed for the second operation.

SUMMARY

1. Emergencies in the allergist's practice arise mostly from intradermal skin testing and from treatment with antigenic extracts.

2. The principal precautionary measures for the avoidance of reactions from skin testing are omission of tests for antigens to which there is a history of pronounced sensitivity and for others which are known to be common sources of generalized reactions (fish, nuts!); avoidance of intradermal tests in children below 6 years of age.

3. With therapeutic injections of antigenic extracts, caution should be exercised to avoid accidental punc-

DERMATITIS FROM WEARING APPAREL

LOUIS SCHWARTZ, M D
Medical Director; Chief, Dermatoses Section
AND
SAMUEL M PECK, M.D.
Senior Surgeon (R), U S Public Health Service
BETHESDA, MD

Dermatitis from most types of wearing apparel has been reported usually as isolated instances. On occasions, however, large outbreaks have occurred among the general population because of the sale of new materials containing substances of unknown toxicologic properties which were placed on the market before testing for action on the human skin

Among articles of wearing apparel, dermatitis has been reported from fabrics such as silk, wool and synthetic fibers, from leather, artificial leather, furs, rubber and rubber containing materials such as rubber gloves, dress shields and girdles, socks, pajamas, brassieres, and many others. Metal and metal alloys used in jewelry and in eyeglass frames, wrist watches and straps have also caused dermatitis. Plastics used in spectacle frames, wrist watch straps, garters and suspenders have also been reported as causes of dermatitis.

FABRICS

While occasional cases of dermatitis have been reported as due to sensitivity to some of the unprocessed fabrics such as silk and wool, the majority of the reported cases of dermatitis due to the wearing of fabrics have been caused by the processed fabrics.

Fabrics as worn by the public consist of the basic fabric itself and all the chemicals which have been placed on them or in them, such as dyes and finishes, in order to make them salable or suitable for wearing purposes.

Sensitivity to Unprocessed Fabrics.—Sensitivity to silk has been reported.[1] Most of the reported cases have been from processed silk Very few authors differentiate between sensitivity to the raw silk and the chemical with which it was treated. The type of eruption described by most of the writers is of the urticarial type. Urbach [2] described an actual case of contact dermatitis from unprocessed silk.

Fabrics made from wool,[3] camel's hair [4] and other animal hairs have been reported as causes of allergic contact dermatitis. There are no cases of dermatitis reported from unprocessed fabric made from vegetable fibers such as cotton and linen, although dermatitis has been reported as occurring among pickers of flax and also from cottonseed oil (oil of gossypii).

A review of the literature of sensitivity to so-called basic fabrics shows that in most instances the sensitivity tests on which the diagnoses were made were performed not with the actual raw materials but with undyed or unfinished fabrics, so-called gray goods, which are already partially processed. Perhaps another fallacy in some of the reported tests has been failure to distinguish between the physical irritation caused by "wooly" or rough fabric and an actual allergic reaction. As a corollary, a dermatitis may be caused by the friction of a rough material where a patch test for the purpose of demonstrating sensitivity would be negative. In such cases the cause may be the mechanical friction resulting from actual wear

Synthetic Fibers.—Fabrics for wear are made of processed cellulose (rayon), of a number of synthetic resins, glass and casein.

Cellulose.—From cellulose is manufactured the various rayons such as viscose rayon and acetate rayon.[5] While many cases of dermatitis have been reported among the wearers of these rayons, all the cases were from the finished product and not from the unprocessed material.

Synthetic Resins.—The best known of the purely synthetic resin fabrics are polymers made from hexamethylenediamine and adipic acid and sold under the trade name of Nylon. Although some cases of dermatitis from nylon have been reported, it was shown that these cases were all caused by a certain finish and not the nylon itself.[6] Fabrics are now being made on a small scale from vinyl and styrene resins as well as from fiber made from casein. No cases of dermatitis have been reported from them.

Glass.—Glass is now being spun into fiber. In order to make these fibers suitable for weaving into fabric, certain resins are used on them. Cases of dermatitis have been reported from such glass fabrics. These

cases are due to the resins or the mechanical irritation of the rather sharp fibers and not to allergy to the glass.

Glass wool is made for insulating purposes. Dermatitis occurs in its manufacture and in its use, caused by the mechanical irritation of tiny sharp glass slugs and occasionally from sensitivity to the resin binder (phenol-formaldehyde) which it contains.[7]

Synthetic Films.—Some of the plastics in sheet form are used for protective clothing. Some of them are also laminated onto cotton or other natural fabrics in order to make them impervious. Rubber hydrochloride, vinyl resins, acrylic acid resins and cellulose acetate are used for these purposes. Dermatitis has been reported from the vinyl, the acrylic acid and the rubber hydrochloride films, but in all these cases it was due either to plasticisers or stabilizers used in the films.[8]

The following plasticisers, stabilizers and modifiers have been causes of dermatitis: tricresylphosphate, triphenylphosphate, dibutyl sebacetate, dibutyl tin delaurate, dibutyl tin laurate maleate, phenyl salicylate and resorcin-formaldehyde combination.

Rubber.—Dermatitis from wearing apparel made of rubber has been reported. Gloves, girdles, dress shields, gas masks, condoms and so on have all been reported to cause dermatitis. In all of these cases it was the compound placed in the rubber, such as the accelerator and antioxidants, or compounds formed on the surface of the rubber by "vapor cure" (sulfur monochloride) which have been the actual irritants, not the rubber itself.[9] The following accelerators, antitoxidants and so on have been the cause of dermatitis: hexamethylenetetramine, the guanadines, mercapto benzothiazole, tetramethyl thiuram monosulfide and disulfide, paratoluidine, orthotoluidine, triethyl trimethyl triamine and the antioxidants phenyl beta naphthylamine and monobenzyl ether of hydroquinone (leukoderma).

The accelerators named are contained in many rubber articles which do not cause dermatitis. They cause dermatitis only when they are contained in the rubber in such quantities that they "bloom" out or if they are so loosely incorporated that they can be leached out by the perspiration. The same statement applies to the antioxidants except monobenzyl ether of hydroquinone. This chemical can cause leukoderma even when it is properly incorporated into the rubber.[10]

Dermatitis from "vapor cured" rubber is caused by the fact that continuous changes take place on the surface of vapor cured rubber, and these changes result in the formation of sensitizing chemicals. Those who develop dermatitis from wearing vapor cured gloves (surgeons) may prevent dermatitis in the following manner: soaking the gloves in a 5 per cent solution of sodium carbonate for fifteen minutes and then rinsing in water; sterilizing by dry heat and wearing them dry and well powdered on the inside of the gloves every time the gloves are to be worn. The same procedure should be adopted by those sensitive to rubber gloves made directly from latex, because in such gloves the accelerators and antioxidants are more easily leached out by the perspiration.

Synthetic Rubber.—There are several types of synthetic rubber. The first one made in America was Neoprene, which is made from acetylene. There are now being manufactured Buna S made from butadiene and styrene, Buna N made from butadiene and acrilonitrile, and butyl rubber made from butylene and isoprene. Although these synthetic rubbers have been on the market for a comparatively short time the little wearing apparel, mostly gloves, has been made from them, some cases of dermatitis have been reported.

These synthetic rubbers are processed in the manner similar to that used for processing natural rubber and contain accelerators and antioxidants and other compounds, cured by heat as well as by sulfur monochloride. Most of the cases of dermatitis from synthetic rubbers are probably caused by the same compounds as cause dermatitis in natural rubber, although synthetic rubber does contain sensitizing substances not present in the natural rubbers.[11]

Dyes and Mordants.—Dermatitis due to fabric dyes is relatively infrequent among the wearers of the fabrics.[12] For some time it was the common impression among physicians that dermatitis due to wearing apparel was caused by the dyes in the fabrics.

When dermatitis is caused by the dyes, it is usually due to an idiosyncrasy to the dye itself or to a faulty process of dyeing, so that there is retained in the fabric some chemical which should not have been present. On occasion, dyes will cause dermatitis if one of the known sensitizing dyes are used.

When dyes themselves have been found to be the cause of the dermatitis it has been usually found that they easily come out of the fabric or "bleed." Condi-

tions on the skin surface may help to determine the "bleeding" of the dyes from the fabric. For instance, some will bleed out in acid perspiration and others in alkaline. Since some of the dyes are soluble in fat solvents, a high fat content on the skin surface may help dissolve them out. It is also to be borne in mind that the dye intermediates are more likely to cause dermatitis than the finished dyes themselves and that under certain conditions, such as the heat of ironing, some dyes will break down into their intermediates.

Faulty dyeing process may cause dermatitis by leaving in the fabric some chemical irritant which should have been removed, as for instance in vat dyeing or in mordant dyeing the excess of the oxidizing or mordanting bichromate should be removed before the dyeing is finished; otherwise dermatitis may occur on those handling or wearing the fabric. Wool is often dyed by the aid of a mordant. Mordants are also used in certain dyeing processes other than wool dyeing. Of the mordants it is the dichromates which have caused dermatitis. The following dyes have been reported as causing dermatitis: amino-azo-benzine, auramine, brilliant indigo 4G, crystal violet, chrysoidine, hydron blue, iso-rosinduline, indanthrene violet R. R., ionamine A, metanil yellow, methyl violet, malachite green, orange R, orange Y, ponsol dark blue B R, sulfanthrene pink F. F., safranine, victoria blue, victoria green and resorcinol component dyes.

Special dyes are used for dyeing of rayon because the ordinary dyes do not easily penetrate the comparatively solid rayon fabric. Dermatitis has occurred from these special acetate dyes.

Fabric Finishes.—It has been shown that in most instances the dermatitis among the wearers of fabrics was caused by the finishes rather than by the dyes.[6]

Finishes are placed in fabrics to give them a better appearance such as luster, better feel and wearing properties, to prevent runs and unraveling, to make fabrics noncreasing and sometimes to hold the crease and to make them waterproof, mothproof, flameproof, moldproof and insectproof. Some of the finishes stay more or less permanently in the fabric. Other finishes are easily removed by the laundering and only a small part may remain after many washings. For this reason finishes which are removed by laundering are reapplied after each laundering.

Starches and sulfonated castor oil were the first finishes used and were applied to enhance the appearance and the feel of the fabric and thus increase its selling appeal. Dermatitis has never been reported from starch, but Schwartz showed that an improperly neutralized sulfonated castor oil (alkalinity) was the cause of a dermatitis from socks.

Antiwrinkle and Crease Holding Finishes.—More recently certain resins have been applied as finishes to make the fabric resistant to wrinkling or to hold its crease and, in the case of stockings, to prevent runs. These resins are usually applied in the dye bath and consist of modified natural or totally synthetic resins. Schwartz and his associates [13] showed that an outbreak of dermatitis thought at first to be due to a synthetic fabric was really due to a finish containing an ester gum. This finish was used on other fabrics and caused dermatitis.

The new synthetic resin finishes have caused a number of cases of dermatitis. The resins are applied from solutions or emulsions which leave a thin film of the resin on the fabric after evaporation of the solvents. The resins, ester gums, the formaldehyde type, methyl methacrylate, vinyl, styrene and glyptal resins may be applied in this manner. Some of the resins when applied in the form of emulsions containing uncured or partially cured resins are completely cured in the heat of the finishing bath and in the heat of the boarding process.

Completely cured resins do not as a rule cause dermatitis. When complete polymerization and stabilization does not occur, there may be enough free monomers or uncured resins remaining on the fabric to cause dermatitis in sensitive cases. Actual sensitization by the fabric can occur also.

Glycerin-phthalic anhydride resins are used in emulsions containing alkali such as ammonia or sodium hydroxide or triethanolamine. These resins may also contain impurities which are skin irritants.

The dicyandiamide-formaldehyde resins may undergo decomposition to form methylamines which may cause dermatitis. Other resins which cause sensitization dermatitis may be introduced into use as fabric finishes.

Waterproof Finishes.—In some of the older methods of waterproofing fabrics (1) the fabric was placed in the soap bath followed by alum or other aluminum salts in watery solution in order to deposit aluminum soap on the fabric or (2) an application of aluminum or lead soap from an organic solvent such as benzene was made. There are no recorded cases of dermatitis from the finished materials proved to be due to waterproofing agents containing these insoluble metallic soaps.

In still another method of waterproofing, the fabric after dyeing and drying is then passed through a solution of paraffin dissolved in a petroleum solvent and again dried over hot cylinders. When Japan wax was used instead of paraffin, dermatitis was seen from such coated fabrics because Japan and China wax are derived from a tree of the poison ivy family (Rhus vernicefera).

Fabrics have been treated with tar or resins and rubberized in order to make them waterproof. Dermatitis has been seen from such materials only among the processors of the fabrics.

Flameproofing.—Canvas and leather gloves, sleeves and aprons are used as a protective by welders to protect them against sparks. These materials may be treated with flameproofing chemicals. Asbestos also is used. Wearers of asbestos do not have dermatitis from it, as it is not worn next to the skin.

Cotton and silk are often flameproofed by treating with chlorinated naphthalenes, ammonium sulfamate, boric acid and borate, diammonium phosphate, antimony chloride or other substances. Although workers making clothing from these materials sometimes develop dermatitis and workers processing fabrics with chlorinated naphthalenes may develop chloracne, cases of dermatitis among the users of these fabrics have not been reported.

Delustering Agents.—Zinc sulfate, barium sulfate, aluminum sulfate and titanium oxides are some of the chemicals used as delustering agents. No dermatitis has been reported from their use.

Mothproofing and Lousicides.—Silico fluorides are most frequently used for [illegible] gh the chlornaphthalenes (naphtha [illegible] chlorphenols, synthetic camphor and others also are used. The solutions of silico fluorides are usually sprayed on the fabrics. The chlornaphthalenes and camphor used in the form of flakes or balls are placed in the clothes

13. Schwartz, L.; Spolyar, L. W.; Gastineau, F. M.; Dalton, J. E.; Loveman, M. B.; Sulzberger, M. B.; Cope, E. P., and Baer, R. L.: An Outbreak of Dermatitis from New Resin Fabric Finishes, J. A. M. A. 115:906 (Sept. 14) 1940.

or closets. Dermatitis has not been reported from fabrics exposed to these substances.

Since the outbreak of World War II, it has been found desirable for sanitary reasons and as a protective measure against typhus to treat clothing of our armed forces with chemicals known to kill lice and other related insects. The most widely used and effective agent at present is DDT (dichlor-diphenyl trichlorethane). It can be used alone or in combination with other insecticides. Other insecticides such as pyrethrum, rotenone (the active principle of derris and cube) and synthetic insecticides may be used.

The synthetic insecticides are usually primary irritants in strong concentrations, and the natural insecticides are sensitizers.

Antimildews.—With the advent of the war it has been found necessary to mildew-proof many articles of clothing and equipment made of fabric and leather to prevent their deterioration in tropical climates. Tenting, hammocks, camouflage and mosquito netting, knapsacks, canvas covers of all types, interlinings of shoes and many other articles have been treated with mildewproofing agents. They are so precipitated on the fabrics that they will be retained after many washings. While many chemicals are excellent fungicides, they cannot be incorporated into articles of clothing or equipment which are to be in close contact with the skin because they are primary skin irritants and sensitizers [14] in the concentrations in which they satisfy antimildew performance specifications against molds. Even if such irritant chemicals are incorporated into materials which are not to be in contact with the skin, such as sandbags and tenting, they have been the causes of dermatitis to the workers making those materials. This does not imply that such chemicals should not be used in fabrics which will not be worn next to the skin.

We have tested many of the compounds which have been suggested by our armed forces as mildewproofing agents by means of the "prophetic patch test" [15] Actual field trials have supported the value of this procedure,

TABLE 1—*Mildewproofing Agents*

	Percentage of Weight of Material

	0.45

when properly carried out, to rule out the use of those chemicals which would cause dermatitis.

The mildewproofing agents listed in table 1 in the incorporated concentrations given have been found to be skin irritants.

When some of the antimildews named in the table were used on fabrics which were also waterproofed by superimposing a wax, the patch tests were negative because the antimildew did not come in contact with the skin. However, under some conditions of manufacture the workers would have sufficient contact to cause dermatitis when the superimposed waterproofing material was rubbed off after continual friction with the workers' skin, thus exposing them to the action of the antimildew.

Leather.—Dermatitis among leather workers is not infrequent because of the many primary irritants and sensitizers used in processing the hides to convert them into leather. However, the incidence of dermatitis due to wearing and handling leather goods is small compared to the millions of users. Dermatitis has been reported from hatbands, gloves, wrist-watch straps, pocketbooks, furs and other leather articles.[16]

Many of the chemicals used in processing hides to convert them into leather may be the cause of the dermatitis, but the tanning agents and the dyes have been found to be the most frequent causes of the dermatitis among the wearers and handlers of the finished leather goods. Recently another source of dermatitis among those exposed to the finished leathers has been introduced by the addition of mildewproofing agents to the leather. We have encountered a number of instances of dermatitis due to these chemicals, but as yet leather containing the mildewproofing agents has not been used for a sufficient time by the general public for reports of such cases to have appeared.

The majority of the cases of dermatitis due to contact with leather have been of the allergic type. The sensitizing chemicals may have been dissolved out of the leather by water or perspiration.

The sensitivity may have been acquired by contact with the chemicals in the leather, or the sensitivity may have resulted from previous contact with similar chemicals used in other articles of wearing apparel. The substances remaining in the leather listed in table 2 may be causes of dermatitis.

Antimildews and Fungicides.—We have found leather in which the following chemicals were used as antimildews capable of producing dermatitis: mercapto benzothiozol, tetrabrom ortho cresol, paranitrophenol, pentachlorphenol, salicyl anilid and dihydroxy dichlor diphenyl methane.

Lollar [17] performed patch tests with seven antimildews contained in leather in concentrations of 0.75 per cent and less and obtained reactions from para-chloro-meta-cresol, phenyl mercuri-acetate, ethyl mercuri phosphate and puratized N-5-X (organic mercurial).

Artificial Leather.—Materials designated as artificial leather may be made from cotton fabrics covered by cellulose nitrate and vegetable oils, synthetic resins or rubber solution, or latex may be impregnated into cotton or loosely felted papers or napped soft felted fabrics. In some instances the cotton fabrics are covered with plastics. Sheets of artificial leather may be made from loose fibers and scrap leather which are compressed after mixing with linseed oil. The grains of the different leather are then put on the surface by embossing machines or engraved press plates. Concentrated uncoagulated pastes of compounded latex and fibers are dried, pressed and vulcanized in another process of making artificial leather.

Dermatitis may occur from such artificial leather from the dyes, the resins, the formaldehyde, sulfur, the antitoxidants and other chemicals used in its manufacture.[18]

Shoes.—Dermatitis from shoes has been frequently reported in the literature.[19] A number of instances of dermatitis from the shoe polish have also been observed. Such instances have been more frequently reported in the European literature probably because Americans are not in the habit of polishing their own shoes as much as the Europeans. It is hard to conceive of a dermatitis from the outer leather of the shoes, since there is very little contact with the skin of the foot. The chemicals incorporated in the outer leather would have to go through the backing and through the socks in order to produce a dermatitis

The inner lining of the shoes as well as the backing contains chemicals which may cause dermatitis. The backing of the shoes contains adhesives, antimildews and fungicides. In a number of instances artificial leather may be used on the inside of the shoe.

Furs.—There are many reported instances of dermatitis due to the handling and wearing of furs.[20] While a dermatitis among the wearers of furs may occur from the mechanical friction of the coarse hairs against the skin or to a sensitivity to the unprocessed fur, such occurrences are rare. In the majority of such cases it is due to the dyes and the tanning agents.

Since the nonhairy hide of the pelt is covered by lining, only the fur itself comes in contact with the skin. Thus the chemicals used for tanning and dressing the fur rarely cause dermatitis, especially since they are present in only traces in the hair of the fur.

It is the dyes and the mordants used with them which are applied to the hairs that cause the dermatitis from wearing of furs. It is necessary for the wearer to be sensitized to these chemicals before the garment is worn or to have been sensitized by wearing the garment in order to develop dermatitis. Furthermore, in order to cause a sensitivity the furs must be so poorly dyed that they are leached out by perspiration or moisture. It is possible that, once sensitivity has developed, even a well dyed fur may cause dermatitis.

Paraphenylenediamine has been the chief cause of dermatitis from fur. The other oxidizing dyes, aniline black and ortho amino phenol, may also cause it. The chrome mordants are also possible etiologic factors.

Paraphenylenediamine is a white crystalline substance which itself is comparatively nonirritant. In using it for a fur it must be oxidized. The first oxidation product is said to be quinone diamine, which is an unstable compound capable of producing local irritation of the mucous membranes. This chemical is said to be the actual cause of dermatitis from paraphenylenediamine. Further oxidation results in the formation of a chemical known as Bandrowski's base, which is not yet the final black oxidation product but is not supposed to be irritant.

The reduction of the incidence of dermatitis among the users of furs is in the hands of the dyers. In recent years they have been aware of this fact and have processed the furs with greater care so that now we rarely see reports of cases. The preventive measures used by the dyers include the use of weak solutions of the dyes frequently applied or applied for longer periods rather than concentrated solutions for short periods, the careful oxidation of the dye and the thorough removal of excess or unoxidized dyes by washing and drumming.

Jewelry.—Dermatitis produced by jewelry has been reported.[21] In most instances it was due to metallic jewelry, but dermatitis can occur from some of the modern jewelry made from various plastics and other materials. Cases of dermatitis from earrings, necklaces, lockets, watches and spectacle frames have been reported.

Most of the reported cases of dermatitis from metallic jewelry have been attributed to the nickel. Such cases of nickel sensitivity have been found among the wearers of watches and spectacle frames made of nickel alloys, among which is the so-called white gold.

Schwartz, L., and Tulipan, L.: Occupational Diseases of the Skin, Philadelphia, Lea & Febiger, 1939, p. 635.

Schwartz and Tulipan report sensitization to platinic oxide in a worker handling this material, but we have been unable to find any instances of dermatitis in the literature from the wearing of platinum jewelry.

Andrews shows a photograph with the legend "dermatitis from chromium wrist watch." No particulars as to the exact cause of the dermatitis are given.

Feathers.—Contact dermatitis from feathers in wearing apparel is a rarity, since most of the wearing apparel made from feathers is used as ornaments on hats or other objects and there is but little contact with the skin. In the past, contact dermatitis due to feathers has been reported mainly among children who had contact with the feathers in pillows and bedding.[22]

DIAGNOSIS

Dermatitis from wearing apparel is not difficult to diagnose. The eruption begins at the place of contact with the offending material, usually five days or more after the garment has been worn. This is the period of incubation for the sensitivity to be established. The eruption may appear sooner if the person is already sensitive to the chemical in the wearing apparel which causes the dermatitis. The eruption is usually confined to the areas of the skin touched by the offending material. In exceptional cases, however, a generalized eruption may be present and sometimes systemic symptoms such as elevation of temperature may accompany the dermatitis.

It is recommended that the following facts be ascertained in order to make an etiologic diagnosis:

1. When did patient buy the wearing apparel?
2. From what firm?
3. Date when wearing apparel was first worn.
4. Date when eruption began.
5. What parts of body were first affected?
6. Extent of eruption.
7. Description of eruption.
8. What previous skin diseases?
9. Has the patient any history of allergy of the skin or the mucous membranes?
10. Were any drugs taken before the present eruption?
11. Did the patient come in contact with poison ivy or other irritant plant before the present eruption?
12. Is the eruption still present?
13. How long after the patient stopped wearing the apparel did the eruption persist?
14. Were patch tests performed? Give details and results.
15. Has the actual chemical in the wearing apparel causing the dermatitis been discovered?
16. What method was employed for determining the actual chemical causing the dermatitis?
17. Give the basic facts on which the diagnosis of dermatitis from wearing apparel was made.
18. What treatment was given?
19. Prognosis.

PATCH TEST

The patch test, properly carried out and interpreted, is the most practical method for demonstrating the actual cause of a contact dermatitis.[23] It has been recently used by manufacturers to determine the possible skin irritating or sensitizing properties of wearing apparel containing new chemicals before placing them on sale to the public.[15]

Technic of the Patch Test.—Before an attempt is made to describe the methods used for patch testing, clear distinction must be made between substances which are primary skin irritants and those which will be called sensitizers. It is obvious that a concentrated solution of a strong acid or alkali will burn or inflame any skin, the degree of injury depending on the concentration of the irritant, the amount applied, the duration of its action and the area to which it is applied.

A group of dermatologists acting as consultants to the Public Health Service have defined a primary skin irritant as follows:[24]

A primary cutaneous irritant is an agent which will cause dermatitis by direct action on the normal skin at the site of contact if it is permitted to act in sufficient intensity or quantity for a sufficient length of time.

Many chemicals which are primary irritants are also sensitizers, for instance, formaldehyde, alkaline bichromates, mercuric salts and phenols.

It is obvious that patch testing with strong concentrations of known primary irritants will result in reactions on any skin. This does not mean that patch tests should not be performed with dilute solutions of chemicals which in strong concentration are primary irritants. There are published lists of concentrations of chemicals which dermatologists have used to determine hypersensitivity; these concentrations, together with the time they are to remain on the skin, are recommended in an attempt to avoid the primary irritant action of the chemical.

The chemicals which are not primary irritants are responsible for the great majority of cases of contact dermatitis caused by wearing apparel, cosmetics, ornaments and the like. They induce a specific skin allergy and thus cause dermatitis.

They may be called sensitizers and were defined as follows by the group of consultant dermatologists:[24]

A cutaneous sensitizer is an agent which does not necessarily cause demonstrable cutaneous changes on first contact but may effect such specific changes in the skin that, after five to seven days or more, further contact on the same or other parts of the body will cause dermatitis.

Substances which are only sensitizers need not be diluted for patch test purposes.

The patch test when used for diagnostic purposes consists in applying a small portion of the suspected substance to a site of normal skin of the patient. This is covered with innocuous impermeable material, which is then sealed to the skin by adhesive plaster. There have been many modifications proposed in order to overcome certain objections.[25]

The diagnostic patch test is performed in the following manner:

With Liquids.—Saturate a piece of four ply gauze ¼ inch square and apply it to uninflamed skin on the arm or back. The liquid from the gauze should not be permitted to trickle from the patch site. For insulation a 1 inch square of nonwaterproof cellophane is used. (Waterproof cellophane consists of regenerated cellulose coated with a water insoluble resin.) This is sealed to the skin with adhesive plaster about 2 inches square. When smaller pieces of adhesive plaster are used, patches are often lost or there is insufficient contact between the test substance and the skin. The reactions which may result from the adhesive plaster are separated from those resulting from the test substance by the uninflamed skin which is in contact only with the cellophane. In performing a number of patch tests, care should be taken to avoid overlapping of adhesive plaster, as this will cause intensification of the adhesive plaster reaction.

With Powders.—In performing patch tests with powders, the powder is placed on a piece of gauze in order to keep the reaction localized. If the gauze is moistened, it holds the powder better than when dry.

With Solids.—When solids insoluble in water are used, it has been found best to dissolve them in a solvent, making a saturated solution, and wetting a piece of gauze with this solution. The gauze is then allowed to dry before being placed on the skin in order to eliminate the action of the solvent. This procedure deposits the precipitated, finely divided substance on the gauze and brings about better contact with the skin.

When the insoluble solid is of a resinous character, the solution may be painted directly on the skin, the solvent allowed to evaporate and the cellophane and adhesive plaster applied. If the resin adheres firmly to the skin, it is not necessary to cover it with the cellophane and adhesive.

It is usually sufficient to leave the patch on for twenty-four hours, but sometimes when patching with low concentrations or with weak sensitizers it may be necessary to leave the patch on for three or four days, but not for more than five days, as the patient may by that time become sensitized to the patch itself. This is especially true of fabrics which contain no strong irritants and to which most people do not react. The reactions should be read not only on the removal of the patches but every day for at least five days thereafter. This is of special importance in testing fabrics. A later reaction indicates a lesser degree of sensitivity than an early reaction.

PATCH TEST WITH ARTICLES OF WEARING APPAREL

Fabrics.—A piece of the fabric about 1 inch square may be left on for two to five days. The reaction should be read each day up to three days after the removal of the patch. Best results are obtained while the dermatitis is still present. If the patch test is positive, the substances incorporated in the material can be ascertained from the manufacturer and tests performed with each of them. If this is not possible, the following procedure can be taken to determine roughly the class of allergens involved:

Soak the fabric in warm, slightly acid water for twenty-four hours to see if the dye bleeds. If it does, the water extract can be concentrated in vacuo and then a patch test can be made with the concentrated dye. In case the fabric is known to be flameproofed, the flameproofing chemical (if soluble in water) is in the solution. If the water extract is colorless, whatever remains after concentration or evaporation is the water soluble finish. Perform patch tests with this.

To remove the water insoluble finish, soak the fabric in ether for a few hours, allow the ether extract to evaporate on a watch crystal and patch test with the residue.

If possible, perform a patch test with the gray goods, i. e. cloth before any dye or finish is applied. This is important to pick up the rare cases of sensitivity to wool, cotton or silk.

Furs.—In patch testing with fur, the test should be carried out with the hairy side of the fur. If it is positive, rub the fur vigorously with a piece of gauze; should the gauze become discolored, the fur is so-called "dirty fur." A patch test should then be carried out with the gauze discolored by the dye. While most cases of fur dermatitis are due to dye, a dermatitis due to fur itself may be found occasionally.

Leather.—The first step in carrying out the patch test is to determine whether the leather is real or artificial. This can often be determined by tearing the leather. To test the leather, moisten a piece about ½ inch square with the patient's own perspiration from the axilla or with a solution approximating the sweat in p_H and patch test in the usual way. A positive patch test indicates a sensitivity to something in the leather.

To determine whether the dye is the cause of the dermatitis, soak a piece of the suspected material in water having the same p_H as perspiration. The material is left in the solution for about an hour and if the dye is dissolved it is said to "bleed." Evaporate in vacuo and patch test with the concentrated dye. If this reaction is negative, the previously positive reaction indicates that there is a sensitivity to the tanning agents or other chemicals which are not easily dissolved out with water.

To test the finishing oils or fats as possible causes of dermatitis, soak the leather in ether for fifteen minutes, pour off the ether into a water glass, evaporate to dryness, smear a piece of gauze with the fatty deposit and apply to the skin.

The other chemicals in the leather can be traced by patch testing with the leather in different stages of manufacture.

If the leather is artificial, the celluloid, rubber, plasticiser, dye or synthetic resin may be dissolved out by a solvent and used for patch tests.

Shoes.—In investigating suspected causes of dermatitis due to footwear, it is useless to patch test with the material on the outside of the shoe.

In investigating a shoe dermatitis, patch tests should be made with the backing. In some instances the leather on the inside of the shoe, such as the tongue, the inner sole and the sock lining, may be the cause of the dermatitis, but rarely if ever the outside leather. The chemical which causes the dermatitis must get through the sock or stocking. Therefore it is worth while to patch test with the sock or stocking (before washing), which should contain the eliciting agent.

Rubber.—In patch testing with sponge rubber, care must be taken to test with both the spongy and smooth surfaces, as in many instances there are differences in reactions obtained from these surfaces.

The dermatitis due to dress shields is often caused by the rubber which they contain; the active irritant is usually the chemical formed on the surface as a result of the acid or vapor cure. Cases of leukoderma in the

axilla have occurred from the antioxidant (mono benzyl ether of hydroquinone) in the rubber portion of the dress shield.

In cases of dermatitis suspected to be caused by elastic girdles, patch tests should be performed with the rubber in the thread as well as with the fabric. The rubber used in girdles is usually made in the same manner as the thin rubber of dress shields.

Jewelry.—In testing with jewelry, first test with the suspected material itself. Articles are rarely if ever made of the pure metal, and even the so-called pure gold and platinum jewelry contains other metals. It is necessary to determine the other metals which make up the alloy and patch test with each metal. In this regard we wish to call attention to the fact that in testing for nickel sensitivity the five cent piece is not a proper material, since it is made of 75 per cent copper and 25 per cent nickel. To test for nickel sensitivity a 5 per cent solution of nickel sulfate should be used. Similarly a one cent piece is not proper metal for testing for a possible copper sensitivity, since a penny in addition to copper contains 5 per cent tin and zinc. All of the silver coins contain 10 per cent copper.

PROVOCATIVE PATCH TEST

When patch testing with a dilute concentration of allergens such as are found in fabrics, the reaction in some cases may be negative even though from the history and by actual exposure the allergen seems to be the precipitating cause. If, however, at the same time the test is performed with the dilute concentration a second patch of a strong concentration is applied, positive reactions will develop at both sites if the actual allergen has been used. We [15] have called this phenomenon the "provocative patch test."

PROPHETIC PATCH TEST

The use of the patch test for the purpose of foretelling whether a substance will or will not produce dermatitis is a recent development and may be called the "prophetic patch test." It was introduced by one of us to determine possible irritant qualities of new chemicals used in the manufacture of wearing apparel, cosmetics or other articles coming in contact with the skin. The patch test is made on 200 or more individuals in the usual way. Since the chemicals or compounds to be tested are new ones, it is presumed that there has been no previous contact with them.

Two series of patch tests are carried out on the same individuals ten to fourteen days apart. The first series of tests would give reactions only with a primary irritant or with people who have been sensitized by previous contact with the chemical. The second series shows the number sensitized by the first series. Experience has shown that even one positive reaction among the second series may indicate that the test substance is a sensitizer which might lead to outbreaks of dermatitis if allowed to be used by large groups of people.

The pieces of material should be at least 1 inch square and allowed to remain on the skin for forty-eight hours. The larger the pieces used and the longer they are permitted to stay on the skin, the more likely we are to approximate actual wearing conditions and the more accurate the results of the test, because the subject is being exposed to larger amounts of the chemical the irritating properties of which are being tested. In a number of instances we have noted failures to induce sensitivity with a small piece of material (¼ inch square) when we succeeded with larger pieces (1 to 2 inches square).

WHEN AND WHERE TO PERFORM PATCH TESTS

The impression seems widespread that patch tests should not be performed while an eruption is still present, because a flare-up of the dermatitis might take place. The period most favorable to a positive reaction is at the time when the dermatitis is still present and active. A relative hyposensitivity may develop when the dermatitis is disappearing or after it has disappeared, with the result that the patch test would tend to be negative. Here too experience and judgment are necessary in choosing the proper time for performing the tests. Obviously when dealing with a patient who has a generalized dermatitis it is better either to wait until the eruption has improved or, if the test is carried out while the eruption is present, to use a low concentration of the suspected chemical.

A generalized eruption following the patch test indicates a high degree of sensitivity. Such eruptions are exceedingly rare. Flare-ups of quiescent eruptions are not uncommon following patch tests. These also indicate high degrees of sensitivity.

In cases of true allergic dermatitis, the skin all over the body is sensitive and patch tests can be applied at any convenient site. The most rapid reaction, all other factors being equal, will take place on the areas of skin where the keratin is thinnest. The thick keratin layer of the palms and soles not only explains the negative patch test which results at these sites but is the main reason why contact dermatitis is only occasionally seen in these locations.

INTERPRETATION AND READING OF PATCH TESTS

It requires considerable experience to interpret reactions to patch tests correctly.

Since the patch test was first employed, gradations of the reaction have been recorded by the symbols 1 +, 2 +, 3 + and 4 +. By this method an erythema on the area of skin to which the chemical was applied is indicated by 1 +, erythema and edema by 2 + and an erythema, edema, papules and a few vesicles by 3 +; erythema, edema, many vesicles and in some cases ulceration are recorded as a 4 + reaction.

The degree of reaction will be greatest at the site of greatest concentration. It is for this reason that weak concentrations of sensitizers must be left on longer. They should be observed for at least five days after the patches are removed. A reaction not present when the patch is removed but which becomes manifest less than five days after the patch is applied is considered a delayed reaction. The delayed reaction indicates that a low degree of specific sensitivity is present or that a weak concentration of the sensitizer was used. To report a patch test reaction properly there should be given (1) concentration of the chemical tests, (2) amount of the chemical used, (3) area of skin contacted, (4) site of application, (5) number of days patch test was left on and (6) periods after removal of the patch on which the readings were made. In this way a more comprehensive appraisal of the reaction in terms of the degree of sensitivity can be made.

The true allergic reaction as a rule increases rather than decreases in intensity for twenty-four to forty-eight hours after the patch test is removed. Reactions of primary irritation with few exceptions tend to subside after the removal of the irritant.

The evaluation of a weakly positive reaction (1 +) depends a great deal on the experience of the one making the patch test. In dealing with a fabric or other substance containing a weak concentration of a sensitizer, a 1 + or 2 + reaction is very significant. This

is especially true in industry, where not only may dermatitis be due to contact with the sensitizer in low concentration but there may be the added factor of friction, with exposure to large amounts of the chemical which is not present in the patch test.

A positive reaction which cannot be reproduced later with the same technic indicates that at the time the patch test was performed the patient was sensitive to the concentration and quantity of the chemical applied. A 1 + reaction which does not persist for twenty-four hours is probably a false positive or is caused by a mild primary irritant, maceration or pressure.

A negative patch test does not necessarily rule out the test substance as a causative agent. The negative reaction might be due to one of three causes: (1) Under the condition of the patch test the actual mechanism which produces the dermatitis is lacking, i. e. patch test does not equal actual conditions of wear, exposure friction, perspiration or the like, (2) the patient is no longer sensitive or (3) the actual sensitizer was not applied.

THE TREATMENT OF HERPES ZOSTER BY PARAVERTEBRAL PROCAINE BLOCK

THOMAS FINDLEY, M.D.
AND
REYNOLD PATZER, M.D.
NEW ORLEANS

A recent discussion of herpes zoster [1] plainly indicates the unreliability of current therapeutic methods but fails to mention the one form of treatment which is likely to provide instantaneous and complete relief from pain. This method, which consists in blocking appropriate sympathetic ganglions with procaine hydrochloride, is not as well known as it should be because to our knowledge it has been described only once in the American literature; the article by Street [2] is a model of clinical writing and deserved wider circulation. However, Rosenak of Budapest [3] had previously reported a larger series of cases. We herein record our experiences with this treatment in 4 cases because we are persuaded that all other methods are obsolete. The total number of cases reported, including our own, is 29 and in only 2 of these was there failure to experience prompt and lasting relief from pain.

REPORT OF CASES

CASE 1.—Mrs. E. M., aged 68, presented a typical and extensive herpetic eruption in the distribution of the second and third left thoracic segments. Large amounts of acetylsalicylic acid and codeine sulfate had given no appreciable relief, and when she was admitted to the hospital on Dec. 19, 1943 she had had virtually no rest for seven days. On December 22, the tenth day of the disease and the sixth day of the eruption, the cervicodorsal and the second and third thoracic sympathetic ganglions on the left side were infiltrated with 1 per cent procaine hydrochloride by means of an anterior approach (fig. 1). Within ten minutes there developed a typical Horner's syndrome with increased warmth and dryness of the skin of the upper part of the back, the axilla, the upper extremity and the inframammary region, pain disappeared completely and no other medication was required. All observers agreed that the vesicles healed much more rapidly than was expected, and by December 27 healing was estimated as 90 per cent complete. There had been no recurrence of pain seven months later.

CASE 2.—L. B., a white man aged 50, had excruciating pain in the left flank and groin for two days before zoster lesions appeared on March 20, 1944. On this day the first, second, third and fourth lumbar ganglions were infiltrated with 1 per cent procaine hydrochloride according to the technic of Ochsner and DeBakey.[4] Some relief was obtained, but we had evidently selected the wrong segments. The following day the eleventh and twelfth thoracic ganglions were similarly injected and thereafter the patient had no more discomfort of any kind. Once again the lesions healed with conspicuous rapidity. Figure 2 shows the lesions on March 23, two days after the second injection. At this time the patient was having no pain whatever.

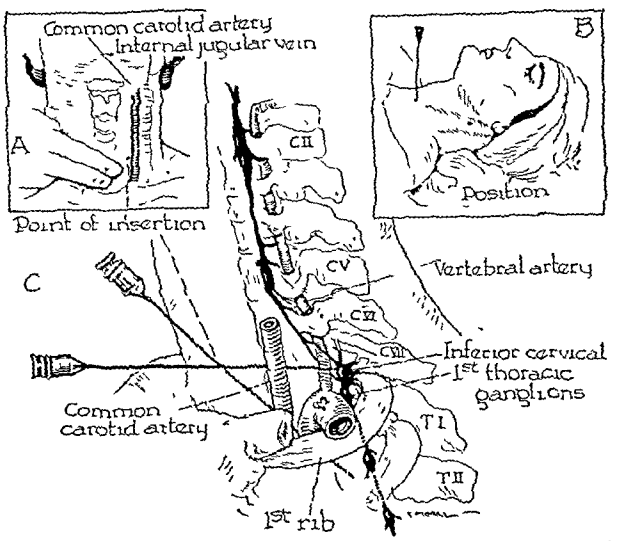

Fig. 1.—Technic of injecting the lower cervical and upper thoracic sympathetic ganglions.

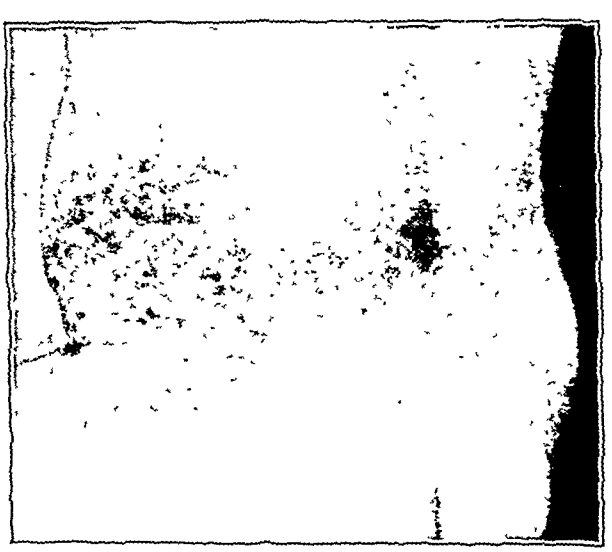

Fig. 2 (case 2).—Lesions forty-eight hours after paravertebral block. At this time the patient was having no pain whatever.

CASE 3.—D. D., a Negro girl aged 7 years, was admitted to Charity Hospital in New Orleans on April 27, 1944 because of a painful herpetic eruption over the left flank and was referred to us by Dr. R. V. Platou. A salve had been previously

applied to the lesions without benefit, and codeine sulfate was given with only slight relief. On April 28 the first, second and third lumbar sympathetic ganglions on the left side were infiltrated with 1 per cent procaine hydrochloride, and complete relief was obtained in ten minutes. The lesions involuted rapidly and by May 12 had almost completely healed

CASE 4.—A. P. L., a white man aged 52, was referred to one of us by Dr. Samuel B. Nadler on Oct. 17, 1944 with the lesions depicted in figure 3; this eruption appeared four days before. On the day of admission an attempt was made to inject the right stellate ganglion according to the technic described. Evidently the needle point was incorrectly placed, because only a fleeting Horner's syndrome developed and the skin of the right side of the face did not become warm and dry. Relief from pain was transitory and incomplete. Forty-eight hours later, however, the injection was repeated with excellent results. From then on he required no analgesics and, when seen a week later, stated that he had had only occasional stinging sensations around the periphery of the zoster eruption and healing was estimated as approximately 75 per cent complete. A third stellate block done at this time afforded satisfactory relief. We think now that more complete relief would have been obtained had the superior cervical ganglion also been injected.

TECHNIC

The technic of sympathetic block is not difficult and is practically without danger if only procaine or allied anesthetic drugs are used and if one is familiar with the anatomy. To block the cervicodorsal and the

Fig. 3 (case 4).—Location of zoster lesions treated by blocking the cervical sympathetic ganglions.

second and third thoracic sympathetic ganglions we prefer the anterior approach. By this method 10 cc. of 1 per cent procaine hydrochloride is used to flood the region of the cervicodorsal ganglions and another 10 cc. to flood the region of the second and third thoracic sympathetic ganglions. The patient is placed in a supine position with the head in the midline and slightly extended. A point is selected two fingerbreadths above the sternoclavicular junction and just medial to the pulsations of the common carotid artery (fig. 1). A 22 gage spinal puncture needle is then inserted straight down, the operator aiming to hit the transverse process of the seventh cervical vertebra. The needle is then withdrawn about 0.25 cm. If no blood is aspirated,

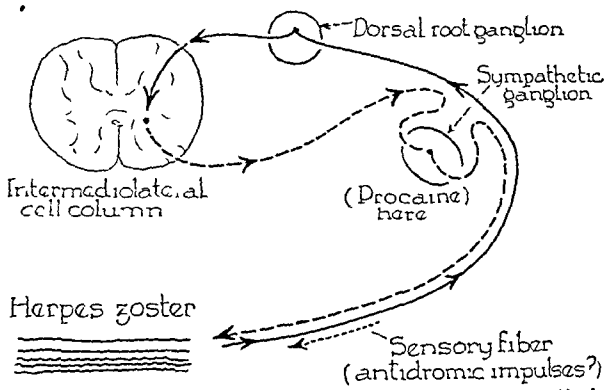

Fig. 4.—Schematic representation of the vicious cycle responsible for segmental vasospasm in herpes zoster.

10 cc. of 1 per cent procaine is injected slowly; the needle is left in place until Horner's syndrome appears; this usually occurs within two or three minutes. The needle is then withdrawn about 1 cm. and directed into the thorax, care being taken to keep it close to the body of the vertebrae near the junction of the transverse process. The region of the second and third sympathetic thoracic ganglions is then infiltrated with 1 per cent procaine hydrochloride.

COMMENT

According to Head and Campbell [5] the essential lesion in herpes zoster consists of an acute inflammatory process involving chiefly the dorsal spinal ganglions together with various degrees of degeneration in the corresponding sensory nerves, dorsal roots and posterior horn cells. This ganglionitis is marked by a round cell exudate, edema, hemorrhage, deterioration of the ganglionic cells and inflammatory changes in the sheaths. The corresponding ventral roots are involved to a much lesser degree, but Bielschowsky [6] found minor changes in the sympathetic chain. The extent of the dermal lesions seems to parallel the intensity of the ganglionitis. Adams [7] has recently reviewed the microscopic picture in detail.

With the location of the primary lesions in mind, it becomes necessary to explain if possible how it is that temporary chemical paralysis of the corresponding sympathetic ganglions, themselves apparently not affected, abolishes pain and promotes healing of the zoster vesicles. The dramatic response to procaine block suggests, of course, that vasospasm must be an important factor, and figure 4 has been constructed to present a tentative hypothesis. Herpes zoster is caused by a filtrable virus closely related to that of chickenpox,[8] although other agents (leukemia, tumor, abscess) are occasionally said to be responsible. In any event the irritative process in the dorsal root ganglion leads to vesicle formation either by peripheral migration of

the virus itself, as seems likely, or by antidromic stimulation of the sensory nerve. At the same time the cells in the corresponding intermediolateral column are receiving an excessive number of normally directed impulses from the irritated ganglion, a circumstance which results in increased sympathetic vasoconstrictor tone and segmental arteriolar spasm. Local axon reflexes may play a minor role, but the essential point is that procaine infiltration of the sympathetic ganglion interrupts a vicious cycle of nerve impulses. Since it is highly unlikely that the results are due to simple blockage of afferent sensory impulses traversing the sympathetic ganglion on their path to the dorsal root, one must assume that the postinjection hyperemia, however transient, relieves pain by dilution of retained metabolites and enhances dermal healing.

Ranson and Von Hess [9] have shown that a weak stimulus to the proximal end of a cut sensory nerve causes vasodilatation but that when the same nerve is affected by a medium or strong stimulus vasoconstriction is produced. Stricker [10] and others [11] have shown that when the distal end of the severed dorsal spinal root is stimulated erythema occurs. Langley [12] noted that when the distal end of the severed dorsal spinal root was stimulated there appeared a small area of erythema with paleness around it. Clinically similar paleness is noted around the herpetic lesions

We have had no opportunity to employ this method in the management of herpes zoster of the face. Hyndman [13] relieved pain in the distribution of the ophthalmic division of the fifth nerve by ablation of the cervicodorsal ganglion, although section of the posterior root of the trigeminal ganglion had failed to do so. This operation was done on the assumption that all the afferent sympathetic fibers from the "scalp, face and neck enter the central nervous system at or below the first thoracic segment." It should be noted, however, that all of Hyndman's cases were of postherpetic neuralgia and that it seems unlikely that efferent preganglionic fibers to the head leave the cord at this low level. If the theory of segmental vasospasm applies to acute cranial nerve herpes, we would expect anesthetization of the cervical ganglions to be ineffective. Should this prove to be true, Dr. Homer Kirgis has suggested to us that procaine block of the otic and sphenopalatine ganglions might give results

SUMMARY

1. Four cases of herpes zoster have been treated by infiltration of the appropriate sympathetic ganglions with procaine hydrochloride. In each instance relief from pain was instantaneous and permanent and the lesions healed rapidly.

2. Regional sympathetic block relieves herpetic pain by abolishing segmental vasospasm.

3. The technic of infiltrating the cervicodorsal and second and third thoracic sympathetic ganglions by the anterior approach is not difficult.

THE TREATMENT OF PNEUMONIA WITH SULFONAMIDES AND PENICILLIN

LIEUTENANT COLONEL J. MURRAY KINSMAN
LIEUTENANT COLONEL WORTH B. DANIELS
CAPTAIN SAMUEL COHEN
MAJOR JOSEPH P. McCRACKEN
CAPTAIN CONSTANCE A. D'ALONZO
LIEUTENANT SAMUEL P. MARTIN
AND
LIEUTENANT WILLIAM M. M. KIRBY
MEDICAL CORPS, ARMY OF THE UNITED STATES

Until recently papers devoted to penicillin therapy have consisted largely of descriptions of the results obtained with this new chemotherapeutic agent, and the interest with which the reports were studied was enhanced by the great scarcity of the antibiotic. Now, however, we are reaching the point at which most descriptions of therapeutic triumphs are merely repetitious rather than informative. The important objective now is to become familiar with the limitations of our new weapon, to gage its usefulness in comparison with the agents it is replacing and to determine the optimal dosage and mode of administration for various diseases. Our purpose in this report is to consider these factors in relation to one of the diseases for which penicillin is most widely used, namely pneumonia.

Of the pathogenic organisms sensitive to penicillin, one of the most susceptible is the pneumococcus. In vitro its growth is completely inhibited by as little as 0.01 to 0.02 unit per cubic centimeter,[1] and in vivo protection tests have repeatedly demonstrated the remarkable ability of penicillin to combat overwhelming pneumococcic infections in mice.[2]

These experimental results have been confirmed clinically in many patients with pneumococcic pneumonia, but the reports have so far consisted mainly of small groups of cases included among presentations of the results obtained with penicillin therapy in general.[3] The one definitive study reported is that of Tillett, Cambier and McCormack,[4] who treated 46 cases of pneumococcic pneumonia, with three deaths. The results in general were excellent, and specific recommendations were made concerning dosage and routes of administration. Eight patients with pneumococcic empyema were also treated successfully with intrapleural penicillin.

One of the striking achievements of military medicine is the reduction in the mortality rate of lobar pneumonia from 28 per cent during World War I to approximately 0.7 per cent during the present war.[5] Many deaths during World War I were of course caused by staphylococcic and streptococcic pneumonias following influenza, but many of these fatalities could have unquestionably

been prevented had our modern chemotherapeutic agents been available.

The present study is concerned with 255 cases of pneumonia, 175 pneumococcic and 80 primary atypical, occurring in soldiers at a large army post from November 1943 until March 1945. There were no fatalities. It must be pointed out, however, that in addition to chemotherapy at least two other important factors are partly responsible for this absence of deaths in a fairly large series. One factor is the youth, vigor and general good health and nutrition of the soldier, and the other is the short duration of time that is allowed to elapse in soldiers between the onset of symptoms and the institution of therapy.

COMPARISON OF THE RESULTS OF TREATMENT OF PNEUMOCOCCIC PNEUMONIA WITH SULFADIAZINE AND PENICILLIN

Although a control series was not reported, it was the impression of Tillett and his associates [4] that in cases of pneumococcic pneumonia treated with penicillin there was a more abrupt fall of the temperature to normal and more rapid clearing of the x-ray than in sulfonamide treated cases. It seemed particularly appropriate, therefore, to compare the temperature and x-ray, as well as other factors, in two carefully studied groups of soldiers, one treated with penicillin and the other with sulfadiazine.

TABLE 1.—*Incidence of Symptoms in the Patients with Pneumococcic Pneumonia Treated with Sulfadiazine and Penicillin*

	Sulfadiazine (% of Cases)	Penicillin (% of Cases)
Prodromes	44	52
Sudden onset	90	92
Chill	94	82
	94	87
	97	87
Dyspnea	75	90
Vomiting	38	36
Headache	77	90
Herpes	19	6
Cyanosis	40	34

One hundred patients with pneumococcic pneumonia were treated with sulfadiazine from November 1943 until March 1944, and 75 patients with penicillin from March 1944 until March 1945. Data concerning the age, race, length of service, duration of illness, clinical symptoms and signs and laboratory data are presented in tables 1 and 2. The similarity between the two groups in every category is striking and would be difficult to duplicate except in an organization such as the army, in which age, health, nutrition and environmental conditions are well standardized. Slightly greater differences were present in the types of pneumococci isolated from the sputum and in the incidence of bacteremia, as shown in table 3. The higher types occurred a little more frequently, and the incidence of bacteremia was slightly lower in the penicillin treated cases, but judging from the clinical and laboratory findings (tables 1 and 2) this was not reflected in the severity of the illness.

Sulfadiazine was administered in an initial oral dose of 4 Gm. followed by 1 Gm. every four hours for from five to seven days, the average total being 37.5 Gm. in 6.1 days. Penicillin was administered intramuscularly for three or four days, according to seven dosage schedules, the details of which are presented in table 6. No manifestations of toxicity were noted with either drug.

There were no deaths, so that the usual criterion in pneumonia therapy, the mortality rate, could not be used in evaluating the results. The factors which were carefully analyzed were the temperature, white blood cell count, x-ray, sputum, complications, relapses and general clinical response.

Three	10%	7%
Four	2%	0%

A striking observation was made in connection with the temperature response. With sulfadiazine there was a gradual fall to normal during the first twenty-four to forty-eight hours, the average being twenty-six hours. With penicillin, on the other hand, the initial fall to normal was more abrupt, occurring in an average of only eighteen hours. In over half (57 per cent) of the patients receiving penicillin there was then a secondary rise in the temperature to over 100 F., which lasted for several hours; in contrast only 9 per cent of the sulfadiazine treated cases showed a similar secondary elevation. The average time required for the temperature to return permanently to normal, including the secon-

dary rise, was twenty-eight hours in the penicillin treated cases, which agrees closely with the twenty-six hour average for the sulfadiazine group. The typical course of a patient treated with penicillin is reproduced in chart 1.

Little difference was noted between the two groups in the time required for the white blood cell count to return to normal (under 10,000) and for complete roentgenographic resolution (table 4). From these figures superiority could be claimed for neither penicillin nor sulfadiazine. The early return to normal of both the white blood cell count and x-ray appearance is undoubtedly due in part to the good general condition of the patients and the short duration of the illness.

In 26 of the patients treated with penicillin, attempts were made daily to isolate pneumococci from the sputum by direct typing and mouse inoculation, and it was found that, although perhaps decreased in numbers, viable, virulent pneumococci could be recovered during and following therapy in every instance for as long as sputum could be obtained.[6] Although the methods used were somewhat different, these observations are essentially in agreement with those of Frisch[7] in sulfonamide treated cases.

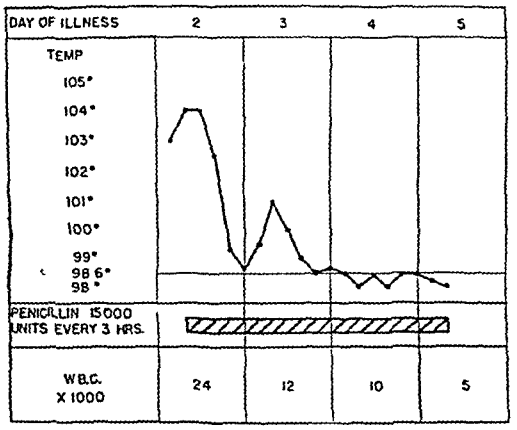

Chart 1.—Typical example of the abrupt initial fall in temperature, with a secondary rise to over 100 F., observed in 57 per cent of patients with pneumococcic pneumonia treated with penicillin.

Complications are listed in table 5. Sterile pleural effusions occurred with approximately the same frequency and severity with the two drugs, and 2 cases of empyema were observed with sulfadiazine, while there were none with penicillin. The 2 instances of spread to another lobe with penicillin both occurred on the second day of therapy, and 1 was questionable because the first x-ray was taken several hours before treatment was begun, so that these changes might have occurred in the interim. With sulfadiazine, however, in 5 cases there was a definite extension to another lobe after the second day of therapy. The 1 case of otitis media occurred two days after penicillin was discontinued in a patient treated for only three days, suggesting that the complication might have been prevented had treatment been continued.

No relapses occurred with sulfadiazine, while with penicillin there were seven. In every instance, however, the dose administered was grossly inadequate. When adequate amounts were administered, clinical relapses did not occur with either drug.

6. These studies of the sputum were made by the Commission on Acute Respiratory Diseases, Fort Bragg, North Carolina, and will be described in detail in a separate publication.

7. Frisch, A. W.: Sputum Studies in Pneumonia, Am. J. Clin. Path. 12:16, 1942.

In both groups there were a number of cases, 10 per cent with sulfadiazine and 4 per cent with penicillin, in which the response to therapy was considerably slower than the average. The temperature and white blood cell count declined slowly over a period of four to six days, and symptomatic improvement was similarly retarded. The clinical course of 1 such patient treated with sulfadiazine is presented in chart 2. The explanation of this lack of an immediate response to therapy is not entirely clear, but in some instances it may have been due to an incorrect diagnosis. It is often difficult to differentiate borderline cases of atypical pneumonia, bacterial bronchopneumonia and pneumococcic pneumonia, and the picture is further confused by the fact that there are probably cases of atypical pneumonia in which there is a secondary bacterial infection. Sulfonamide resistant pneumococci could have been responsible for some of the refractory cases; unfortunately, sensitivity tests were not performed. As far as can be determined, penicillin resistant pneumococci have not been encountered clinically.

DETERMINATION OF MINIMAL EFFECTIVE THERAPEUTIC DOSE OF PENICILLIN IN TREATMENT OF PNEUMOCOCCIC PNEUMONIA

Attempts were made to determine the smallest amount of penicillin which would give satisfactory clinical cures in cases of pneumococcic pneumonia. The cases were divided into five groups, with gradually diminishing amounts of penicillin, as indicated in table 6. The clinical results were good until the total dose was reduced to 60,000 units administered over a three day period. With this amount, in 5 cases there were two clinical relapses and 1 failure to respond to treatment; the other 2 patients showed an excellent response. To illustrate the initial effect of these small doses and the failure to prevent a secondary spread of the infection, the course of 1 of the patients in whom there was a clinical relapse is presented in chart 3. These results are in close agreement with those of Tillett and his associates,[4] who also noted relapses when the amount of penicillin administered was less than

TABLE 5.—*Complications Occurring During and Following Therapy of Pneumococcic Pneumonia with Sulfadiazine and with Penicillin*

	Cases Treated with

120,000 units in three days. The relation of these observations to the optimal dosage will be considered in the comment.

THE TREATMENT OF PRIMARY ATYPICAL PNEUMONIA WITH PENICILLIN

It is now well established that the course of atypical pneumonia is not altered by treatment with the sulfonamides.[8] The disease is presumably also refractory to

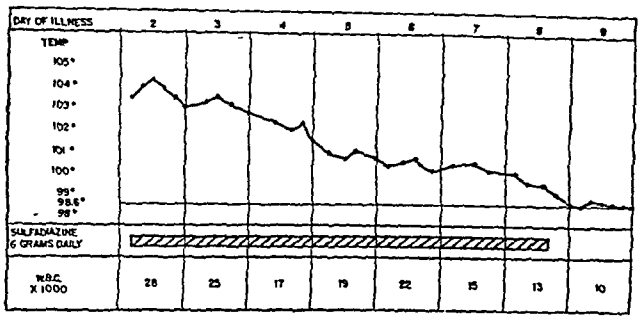

Chart 2.—Patient with the typical clinical picture of pneumococcic pneumonia (type VII) in whom the response to sulfadiazine therapy was much slower than usual.

penicillin, although certain recent evidence casts some doubt on this supposition. Thomas and his associates have isolated from patients a penicillin sensitive nonhemolytic streptococcus which is thought to be closely associated with atypical pneumonia, although a direct etiologic relationship is not claimed,[9] and it is theoretically possible that the action of penicillin against this organism might be of therapeutic value. Further, a more rapid clinical response and fall in temperature in penicillin treated cases than in nontreated patients is described in a recent report from the South Pacific.[10] The author points out, however, that the results cannot be regarded as more than suggestive since the number of cases is small.

Accurate evaluation of therapy in atypical pneumonia is difficult because of the extreme variability in the course of the disease. In single, isolated cases an apparent beneficial effect is often noted with penicillin; the course of 1 such patient who was seriously ill and recovered promptly following penicillin therapy is pre-

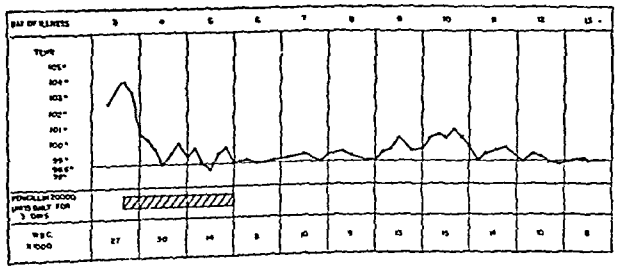

Chart 3.—Clinical relapse in a patient with pneumococcic pneumonia (type XXVIII) who received a total dose of only 60,000 units of penicillin.

sented in chart 4. In view of the natural variations of the disease, no conclusions can be drawn concerning the value of penicillin in this single case. Therapy can be evaluated only by treating a relatively large number of cases and comparing the results with those of suitable controls.

Accordingly, 40 patients with moderately severe atypical pneumonia were treated with penicillin 10,000 to 15,000 units every three hours intramuscularly for three days. The criteria used in selection were (1) duration of symptoms of less than five days, (2) initial temperature of over 102 F., (3) characteristic clinical and roentgenographic picture of atypical pneumonia and (4) initial white blood count under 10,000. Forty cases fulfilling the same requirements were selected for controls, and in both groups the time required for the temperature to return to normal following entry to the hospital was determined. The data and results are presented in table 7. The temperature was elevated for an average of 4.5 days for the treated cases as opposed to 5.2 days for the controls, a difference which cannot be regarded as significant. Further, there was no appreciable alleviation of symptoms or more rapid clearing of the x-ray when penicillin was administered. It can be concluded that penicillin has no beneficial

TABLE 6—*Efficacy of Various Dosage Schedules of Penicillin in Pneumococcic Pneumonia*

Group	Number of Cases	Treatment Schedule	Days of Treatment	Total Amount of Penicillin, Units	Failures or Relapses
		Penicillin in Saline			
1	10	30,000 units I.V.; beginning 1 hour later, 20,000 units every 3 hours I.M for 8 doses; then every 4 hours for 18 doses	4	570,000	0
2	20	15,000 units I.M. every 3 hours for 24 doses	3	360,000	0
3	10	15,000 units I.V.; beginning 1 hour later, 10,000 units I.M. every 3 hours for 23 doses	3	255,000	0
4	10	10,000 units I.M. every 3 hours 4 times daily for 3 days	3	120,000	0
5	5	5,000 units I.M. every 3 hours 4 times daily for 3 days	3	60,000	3
		Penicillin in Beeswax Oil			
6	12	100,000 units twice daily for 2 days, then once daily for 2 days	4	600,000	0
7	8	100,000 units once daily for 4 days	4	400,000	4

therapeutic effect on the course of atypical pneumonia. In seriously ill patients, however, in whom the outcome is uncertain and a secondary bacterial infection might mean the difference between recovery and death, the policy in this hospital is to administer penicillin 10,000 to 15,000 units every three hours intramuscularly until the patient is past the critical stage.

NEWER METHODS OF PENICILLIN ADMINISTRATION

Intramuscular injections of penicillin at frequent intervals (usually every three hours) are painful to the patient and time consuming for the nurse or doctor. Two methods of avoiding these difficulties which show considerable promise, but which are still in the experimental stage, are the intramuscular injection of penicillin-beeswax mixtures[11] and the oral administration of penicillin in various vehicles.[12]

During the last three months of this study, 20 patients with pneumococcic pneumonia were treated in this hos-

pital with penicillin-beeswax mixtures. The concentration of beeswax varied from 4 to 8 per cent, with 100,000 units of penicillin in each cubic centimeter of the mixture. In 12 patients 1 cc (100,000 units) was injected every twelve hours for two days and once daily for another two days, a total of 600,000 units in four days (table 6). The other 8 received 1 cc. daily for four injections, a total of 400,000 units in four days. In 16 of the 20 patients the response to therapy was excellent, in 3 there was a clinical relapse following cessation of treatment and in 1 the pneumonia continued to spread in spite of penicillin-beeswax therapy but responded immediately when, after three days, 15,000 units of penicillin in saline solution was administered every three hours. These four unsatisfactory responses to treatment all occurred in the group receiving 100,000 units once a day only, so that for many hours during each day effective concentrations of penicillin were not present in the tissues. It is of interest that these failures occurred with 400,000 units of penicillin in beeswax and peanut oil, whereas with penicillin in saline solution uniformly good results were obtained with a total of only 120,000 units.

The course of a patient who showed a good response to penicillin-beeswax therapy is presented in chart 5. Assays of the blood and urine are included, demonstrat-

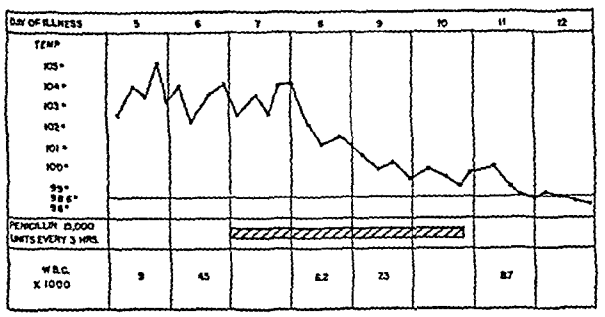

Chart 4.—Patient seriously ill with extensive bilateral primary atypical pneumonia, requiring oxygen therapy, in whom improvement was first noted shortly after institution of penicillin therapy

ing the prolongation of the action of penicillin. The concentrations of penicillin and beeswax in the present preparations are probably not optimal, and in general it may be said that the outlook for obtaining excellent results with one, or at most two, injections daily seems very good.

We have had no experience with oral penicillin in the treatment of pneumonia, but McDermott and Bunn [12] report excellent results A considerable amount is destroyed or lost in the intestinal tract, so that the amount required is several times as large as that needed for intramuscular injections. However, increasing production of penicillin, plus the fact that oral preparations do not need to be as highly purified as those used for intramuscular injections, may soon overcome this disadvantage.

COMMENT

In the present study, results obtained in the treatment of pneumococcic pneumonia with penicillin and sulfadiazine were almost identical, the only differences being a more abrupt fall in the temperature, and fewer instances of extension to another lobe during therapy, with penicillin. It is not to be inferred, however, that penicillin and sulfadiazine are therefore of equal value in the treatment of all cases of pneumococcic pneumonia, for such is not the case. The patients in the present series were vigorous, healthy young adults in whom treatment was instituted early and in whom the response to any adequate therapy should be favorable.

It should be further pointed out that these cases are not comparable to those observed in civilian hospitals,

TABLE 7.—*Comparison of 40 Treated and 40 Untreated Cases of Moderately Severe Atypical Pneumonia with Penicillin*

	Untreated	Treated
Average duration of symptoms prior to admission	3 7 days	3 2 days
Average initial white blood cell count	8,800	9,700
Average initial temperature	102 4	102.1
Average days of fever	5 2	4 5

in which the lower types of pneumococci predominate and in which the incidence of bacteremia is much higher than the 5 to 8 per cent in the present series. The absence of deaths is also difficult to evaluate in view of the likelihood that in this group of healthy young adults the mortality rate would have been relatively low with no specific therapeutic measures whatever. A final word of qualification should be added concerning the diagnosis, which is, as pointed out previously, admittedly difficult in borderline cases seen early in the course of the illness, even with the criteria of chills, fever, pleuritic chest pain, rusty sputum, leukocytosis, x-ray infiltration and, in most instances, isolation of pneumococci from the sputum.

The important conclusion to be drawn, then, is that since adequate doses of either drug will produce an

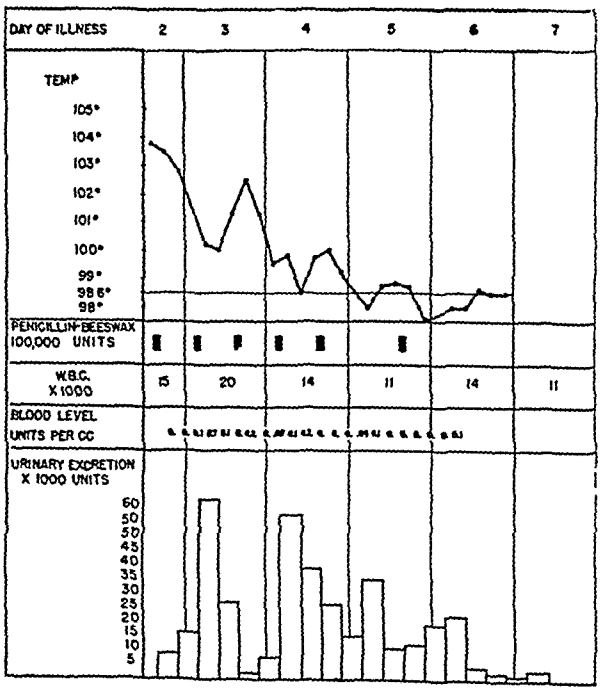

Chart 5.—Response of a patient with pneumococcic pneumonia (type I) to penicillin-beeswax therapy. Assays of the blood and urine are included.

equally satisfactory and, indeed, almost identical response, the lower cost and greater ease of administration may make sulfadiazine the drug of choice for this group of patients. Once the problems of cost and administration are overcome, however, penicillin will be favored because of its lack of toxicity and the probability that penicillin resistant strains of pneumo-

cocci will be encountered rarely if at all, whereas with the sulfonamides resistant strains occur in 2 to 6 per cent of the cases.[13]

Patients seriously ill with pneumococcic pneumonia should be treated with penicillin because of its greater antibacterial action. No large series is yet available, but from the dramatic results obtained in isolated cases [3] there is every reason to believe that the mortality rate of 6 to 10 per cent in civilian hospitals with the sulfonamides may be significantly reduced by penicillin. In addition to its use for patients seriously ill with pneumococcic pneumonia, penicillin is also the drug of choice at the present time for (1) patients sensitive to the sulfonamides, (2) patients with renal damage, (3) pneumonias caused by sulfonamide resistant pneumococci, (4) pneumonias in which the etiologic organism is the staphylococcus or beta hemolytic streptococcus and (5) complications of pneumococcic pneumonia, including empyema, meningitis and endocarditis.

Whether penicillin and sulfadiazine should ever be given together is questionable and involves the highly controversial subject of the possible synergistic action of penicillin and the sulfonamides. It is agreed that the action of the two together is greater than that of either one alone; the dispute centers about whether the resultant action is merely additive,[14] or whether the two combine to produce an action greater than that of the sum of the two separately, i. e., true synergism.[15] We favor the former view and are of the opinion that the bacteriostatic action of the concentrations of penicillin used clinically is so great that no significant difference is produced by the concomitant administration of a sulfonamide. This subject is reminiscent of the sulfadiazine plus antipneumococcus serum controversy, and the result is likely to be similar; in the end penicillin will probably be used alone.

Among the most important points brought out in the present study are the observations concerning the relationship between the mechanism of recovery in pneumococcic pneumonia and the proper therapeutic dose of penicillin. The presence of viable, virulent pneumococci in the sputum during and following therapy indicates that, similar to the sulfonamides, the action of penicillin is, broadly speaking, merely to inhibit the growth of the organisms and localize the infection. Actual recovery is brought about by the body's own defense mechanisms, the so-called "immunologic crisis" occurring usually about the sixth to the eighth day after the onset of the illness. Therefore it is important with penicillin, as with the sulfonamides, to administer treatment during most of this period in order to prevent a spread of the infection. As long as adequate amounts are given, the duration of treatment is more important than the size of the individual dose; for example, it is more rational to give 10,000 units every three hours for six days than 40,000 units every three hours for three days. This point is well illustrated by the complete absence of clinical relapses in the 100 cases treated with sulfadiazine for an average of 6.1 days. The results with penicillin are not strictly comparable, since the 2 failures to respond to treatment and the 5 clinical relapses were probably due more to inadequate doses of penicillin than to discontinuing therapy too soon. When adequate doses (120,000 units or more) were administered, three days of treatment gave excellent clinical results in these moderately severe cases. From our knowledge of the mechanism of recovery, however, it would certainly seem that, at least in seriously ill patients, treatment with penicillin should ideally be continued for five or six days. In order to conserve penicillin and to allow the patients to sleep through the night, penicillin is often administered only four times a day, allowing a period of almost twelve hours during which, for all practical purposes, no penicillin is present in the tissues. This scheme, first employed in pneumonia by Tillett and his associates,[4] has also been used in the present study and is unquestionably effective in many cases of lobar pneumonia. In the more severe cases, however, treatment should be given every three hours night and day, and the total duration of therapy should be at least five days. Specific treatment schedules which can be recommended are as follows: for moderately severe cases, 10,000 to 15,000 units every three hours four times a day for four to five days, and for seriously ill patients 15,000 to 20,000 units every three hours night and day for five or six days. Of course, if the temperature has not returned to normal and the patient has not shown an adequate clinical response, more prolonged treatment may be necessary.

With the newer methods of administration, penicillin-beeswax mixtures intramuscularly and oral penicillin, it may be possible to maintain an effective concentration of penicillin in the blood stream throughout the period of treatment. Although there are certain theoretical advantages to intermittent therapy, no convincing evidence has appeared to challenge the view that, as with the sulfonamides and other chemotherapeutic agents, the best results are likely to be obtained with a continuous effective blood level. For this reason, and because of the greater ease of administration, the present intermittent therapy will probably soon be replaced by these newer methods.

SUMMARY AND CONCLUSIONS

1. A study of the results obtained in 100 cases of pneumococcic pneumonia in soldiers treated with sulfadiazine and 75 treated with penicillin revealed that the response in the two groups was almost identical, the only differences being a more abrupt fall in the temperature, and fewer instances of extension to another lobe during therapy, with penicillin.

2. In studies designed to determine the minimal effective therapeutic dose of penicillin, 10,000 units four times daily for three days intramuscularly produced clinical cures in every instance, but with smaller doses there were relapses and failures to respond to treatment.

3. The clinical course of 40 patients with moderately severe primary atypical pneumonia, as compared with 40 controls, was not altered by treatment with penicillin.

4. Of 20 patients with pneumococcic pneumonia treated with penicillin-beeswax-peanut oil mixture, 12 made an uneventful recovery following six injections of 100,000 units (1 cc.) given over a four day period. Of the other 8 who received four injections of 100,000 units (1 cc. daily) over a four day period, 4 made an uneventful recovery, 1 failed to respond to treatment, and in 3 there were clinical relapses when treatment was discontinued.

CONTINUOUS CAUDAL ANESTHESIA AS A TEST IN THE SELECTION OF HYPERTENSIVE PATIENTS FOR SYMPATHECTOMY

HENRY I. RUSSEK, M.D.; JAMES L. SOUTHWORTH, M.D.
STATEN ISLAND, N. Y.
AND
BURTON L. ZOHMAN, M.D., BROOKLYN

The various methods now employed in the selection of patients for thoracolumbar sympathectomy appear to be unsatisfactory. Certainly no single test has been used which is capable of yielding reliable data as to whether or not sympathectomy will favorably influence hypertension. As the hypertensive state in man "appears to be the result of a number of different factors joining together in an infinite variety of combinations," careful evaluation of the neurogenic component seems essential for a decisive answer to the problem of selection. The sodium amytal, sodium nitrite and cold pressor tests have been found of limited prognostic value in relation to surgery, since they provide an inaccurate index of "sympathetic tone." Thus, poor results have been reported in many cases in which these tests had forecast a favorable outcome.

The observations of Hingson and Edwards,[1] as well as our own,[2] have convinced us that continuous caudal anesthesia may be effectively employed to produce functional denervation of the splanchnic vascular bed similar to the anatomic sympathetic block of the Smithwick operation. Furthermore, if the effects of the two procedures are strictly comparable the caudal anesthesia test might prove of value in identifying those patients who will respond to surgical sympathectomy with a favorable fall in blood pressure.

Accordingly, continuous caudal anesthesia with use of a 1.5 per cent solution of metycaine was carried out on 25 hypertensive patients. The upper level of skin anesthesia was maintained in the region of the fifth or sixth thoracic segments. By this means transient nerve block was obtained of strikingly similar distribution to that more permanently secured by surgical sympathectomy. Eighteen of the 25 patients so studied showed an appreciable fall in blood pressure to normotensive or hypotensive levels, the response suggesting a "neurogenic"

Response of blood pressure to continuous caudal anesthesia (metycaine). Solid line, systolic; broken line, diastolic; T, thoracic level of anesthesia.

origin of the hypertension, as shown in the accompanying chart. In 7 patients there was little or no alteration in the blood pressure as the result of this test, implying a humoral origin of the hyperpiesia ("essential" hypertension).

Lumbodorsal splanchnicectomy was performed according to the Smithwick technic on 5 of the "neurogenic" hypertensives and on 2 of the "essential" hypertensives. The caudal anesthesia test appeared to predict accurately the outcome in all 7 cases. Furthermore, the levels of blood pressure obtained under caudal anesthesia showed a striking correlation with the blood pressure readings following surgical sympathectomy, as shown in the table.

Results of Studies

Case	Age	Blood Pressure * Before Test	Blood Pressure * Caudal Test	Blood Pressure * Post-operative †	Comment
1	44	200/130	140/ 90	136/ 90	Grade 3 eyegrounds; normal cardiac and renal functions
2	42	230/126	140/100	150/ 94	Grade 2 eyegrounds; normal cardiac and renal functions
3	21	200/140	163/128	180/130	Grade 4 eyegrounds; early congestive heart failure, poor kidney function
4	36	180/130	90/ 70	96/ 62	Grade 1 eyegrounds; normal cardiac and renal functions
5	46	160/110	176/110	184/108	Grade 1 eyegrounds; normal cardiac and renal functions
6	45	210/130	136/ 86	140/ 92	Grade 2 eyegrounds; normal cardiac and renal functions
7	47	220/140	120/ 84	126/ 90	Grade 2 eyegrounds; normal cardiac and renal functions

* All pressures were measured with the patient lying down.
† Postoperative follow-up was one to six months.

The method appears to be safer than high spinal anesthesia and is more easily controlled. No significant untoward reactions were encountered. It is hoped that other clinics will undertake to evaluate this test further.

A CASE OF HEMOLYTIC ANEMIA RELIEVED BY REMOVAL OF AN OVARIAN TUMOR

EDGAR JONES, M.D., AND CLIFFORD TILLMAN, M.D.
NASHVILLE, TENN.

West-Watson and Young [1] in 1938 reported an instance of hemolytic anemia being relieved after removal of a dermoid cyst of the ovary with simultaneous removal of the gallbladder. A splenectomy performed four months before had been without benefit. They felt that removal of the ovarian tumor was responsible for relief rather than removal of the gallbladder, since cholecystectomy, which is performed frequently in hemolytic anemia, apparently does not affect the hemolytic process.

In 1939 Watson [2] reported a case of hemolytic anemia in a 17 year old girl which was not relieved by removal of an ovarian cyst (type not stated) but relief followed splenectomy.

Singer and Dameshek [3] described in 1941 a patient with a hemolytic anemia not benefited by splenectomy but relieved by removal of a dermoid cyst of the ovary six months after splenectomy.

We have recently observed a woman with a similar type of anemia who had cessation of a hemolytic process following removal of an ovarian tumor. At the same operation much of the small intestine was freed from a capsule of fibrous tissue.

REPORT OF CASE

Mrs. C. B., a white woman aged 35, a nurse, first seen at Vanderbilt University Hospital in January 1942, complained at that time of pain at various sites, mostly of the extremities, and of a widespread, painful, erythematous skin eruption. Pain in the calves of her legs had begun four years previously; skin lesions had appeared two years previously, and for one year the patient had had swelling of her face. For six months her hands and forearms had been turning blue and became painful on exposure to cold. There had been no loss of weight.

Dr. Homer L. Skinner performed the surgical operations.

In 1939 she had a spontaneous abortion at six weeks gestation; one year later an eight months pregnancy terminated in stillbirth. No information about the fetuses was available. For the previous year menstrual flow had been diminished in amount.

Physical examination on the first visit to this hospital showed her to be well nourished. There was a brownish pigmentation of the skin of the cheeks, neck and anterior axillary folds. There was a fusiform swelling of the fingers, and the overlying skin was shiny and atrophic and in areas was adherent to underlying tissue. There was a blotchy, red discoloration of her hands with focal areas of depigmentation. There was moderate periorbital edema. The thyroid isthmus and right lobe were diffusely enlarged. The heart and lungs were normal. Tenderness was pronounced in the muscles of the arms but was less severe in the muscles of the shoulder girdle and forearms. There were no further significant physical findings. The red blood cell count was 3.63 million per cubic millimeter, with 12 Gm. of hemoglobin per hundred cubic centimeters. The white blood cell count was 5,400 per cubic millimeter, with a normal differential count. The sedimentation rate was not increased. The urine was normal, and an electrocardiogram showed nothing abnormal. Fluoroscopy of the chest revealed no abnormality. Total serum protein was 7.19 Gm. per hundred cubic centimeters, with albumin of 4.33 Gm. and globulin of 2.86 Gm. per hundred cubic centimeters. Basal metabolism rates on two occasions were within normal limits. A diagnosis of dermatomyositis was made at that time.

Late in 1942 the patient was admitted to the Mayo Clinic, where the diagnosis of dermatomyositis was confirmed by muscle biopsy. There she was given "oxygen therapy," wheat germ oil, intravenous typhoid vaccine and a high caloric, high vitamin diet, all without benefit. She was then given sulfathiazole but developed a rash, nausea, edema and fever, so this drug was discontinued.

She was able to continue her work as a nurse until October 1942, when weakness and pain forced her to stop. Three months later she resumed work but had to stop again after six weeks. Throughout 1943 there was gradually increasing disability. In November 1943 her abdominal wall became covered with large vesicles which coalesced, followed by extensive exfoliation.

In January 1944, while in Ohio, she developed acute abdominal distention with nausea and vomiting and was admitted to a hospital, where a diagnosis of intestinal obstruction was made. This was treated by Wangensteen suction, rectal tube and parenteral fluids with gradual relief. She lost 17 pounds (8 Kg.) during a twenty-six day stay in that hospital. She was given one whole blood transfusion from her husband (both being type A) and had a chill. She believed she was jaundiced following this but was not certain. It is not known whether she was anemic at that time. A pelvic mass was felt and was thought to be the cause of the obstruction. She returned to Nashville and was admitted to a local hospital for consideration of operation. There she was found to be emaciated, weak and quite pale. A plain film of her abdomen showed what were apparently gallstones and what was interpreted as enlargement of the left kidney. On admission her red blood cell count was approximately 3 million, with 5 Gm. (?) of hemoglobin. Her reticulocyte count ranged from 8 to 10 per cent. She was given three transfusions of whole blood, with increasingly severe reactions. She became jaundiced after each transfusion, with much nausea and vomiting. Approximately one month after that hospital admission her red blood cell count had fallen to 1.75 million, with a hemoglobin of 5 Gm. She had become greatly debilitated.

It was suspected at that time that she was Rh negative. Such was the case and her husband was found to be Rh positive. She was then readmitted to Vanderbilt University Hospital.

On admission to this hospital on April 11, 1944 the patient appeared chronically ill. Her skin showed the changes of dermatomyositis. The skin and buccal mucous membranes were decidedly pale, as were the scleras, retinas and nail beds. The scleras showed a slight icteric tint. To the right of the umbilicus was a palpable, rounded, tender mass. This was found only intermittently; at times the abdomen was quite flat in this region. On pelvic examination another mass was felt which was thought to be a uterine fibroid.

On admission her red blood cell count was 2.04 million, composed largely of spherocytes; the white blood cell count was 5,500, with a normal differential; hemoglobin was 7.5 Gm.

Urine and stool examinations were essentially negative. A reticulocyte count on admission was 2.6 per cent and one week after admission was 20 per cent. The icterus index was 27.

Blood was sent to Dr. Louis K. Diamond of the Blood Grouping Laboratory in Boston, where confirmation of Rh negativity was obtained. At the same time it was found that her serum agglutinated not only group O, Rh positive cells but also group A and group O, Rh negative cells. It was demonstrated that cold agglutinins were not present. The nature of these panagglutinins has not been determined to date.

Fragility test showed increased fragility of the patient's cells.

Patient: Hemolysis began at 0.52 per cent, complete at 0.38 per cent.

Control: Hemolysis began at 0.46 per cent, complete at 0.38 per cent.

An attempt was made to demonstrate autoagglutinins, but these could not be demonstrated.

Repeated attempts to find compatible blood for transfusions were to no avail, though all cross matching was done with Rh negative blood. Three lots of pooled plasma were found

to agglutinate her cells. Two lots of type A plasma were found to cause no agglutination and she was given 500 cc. of this on successive days. She went progressively downhill, becoming increasingly anemic. Seventeen days after admission the red blood cell count had dropped to 1.93 million, with a hemoglobin of 5.8 Gm.

It was then suggested by Dr. J. K. David that her pelvic tumor might be a dermoid cyst of the ovary in light of the report of Singer and Dameshek. In spite of her extremely poor condition an exploratory laparotomy was advised. This was performed by Dr. L. W. Edwards on May 5, almost one month after admission. When the abdomen was opened a considerable amount of straw colored, mucoid material was found free in the peritoneal cavity. Much of the small intestine was contained in a large fibrous capsule; in addition to this a large right ovarian cystic tumor was found. The capsule was stripped away, the intestine freed and the ovarian cyst removed. During the first five postoperative days, three transfusions of type A pooled plasma, 500 cc. each, were given without reaction. It was noted on the day after operation that one lot of type A plasma which had caused appreciable agglutination of her red blood cells was at that time entirely compatible. During the twenty-six days following operation, without whole blood transfusions, the red blood cell count rose from 1.9 million to 3.17 million and the hemoglobin from 5.4 Gm. to 8.5 Gm. Reticulocytes dropped from 20 to 3 per cent, and the fragility test became normal with hemolysis beginning at 0.48 per cent and completed at 0.38 per cent saline. No spherical red blood cells were seen at that time. On microscopic examination the ovarian cyst was found to be a pseudomucinous cystadenocarcinoma. She was discharged on the twenty-sixth postoperative day much improved.

Following discharge in June 1944 the patient continued to do well except for slight exacerbations of her dermatomyositis. In November she began having severe cramping pains in her legs, which were partially controlled by the use of quinine. Her red blood cell count rose progressively from 3.17 million at discharge to 3.8 million by the middle of November. Her hemoglobin rose from 8.5 Gm. to 11 Gm. and the packed cell volume from 27 to 32 per cent in this period. Reticulocyte counts remained around 3 per cent.

On Nov. 22, 1944 she was readmitted to this hospital thirty-six hours after the onset of severe abdominal pain, distention, nausea and vomiting. A diagnosis of acute intestinal obstruction was made, and she was operated on several hours after admission. A large adhesive band was found obstructing the lower ileum. This was cut, with immediate relief of the obstruction. The intestine at this time was entirely free and appeared normal in color. There were no signs of recurrence of the ovarian tumor. The postoperative course was complicated only by an acute parotitis, which disappeared after the administration of 280,000 units of penicillin over a three day period.

On this admission the red blood cell count was 3.30 million, hemoglobin was 11.8 Gm. and the white blood cell count was 5,000. Reticulocytes were less than 1 per cent. At the time of discharge on the twenty-sixth postoperative day her red blood cell count was 3.37 million, with 9 Gm. of hemoglobin.

Since leaving the hospital she has had considerable pain in her extremities similar to that suffered earlier in the course of her dermatomyositis. On Feb. 21, 1945 her red blood cell count was 4.12 million, with 12 Gm. of hemoglobin.

COMMENT

It appears highly probable that removal of the ovarian tumor in our patient accounted for the improvement of her hemolytic anemia. That removal of the fibrous capsule about much of the small intestine played any part in relief of the anemia seems most unlikely. Granting that some degree of intestinal stasis was caused, any anemia resulting would be expected to be macrocytic in type.[4] The anemia here described was essentially normocytic and normochromic. Many of the red blood cells were spherical prior to operation. This cell type disappeared following operation. It would seem that some material elaborated by the ovarian tumor acted as a hemolysin. According to the concept of Dameshek and Schwartz,[5] spherocytosis with consequent hemolysis resulted from the action of this "hemolysin" on the red blood cells. Although hemolysis was arrested following removal of her tumor, all of her various agglutinins were found by the Blood Grouping Laboratory of Boston to be undiminished three months after operation.

As far as can be determined, ours was the first instance in which removal of an ovarian tumor alone sufficed to effect pronounced improvement in a hemolytic process. Two other reports mentioned record relief of hemolytic anemia following removal of an ovarian tumor when previous splenectomy had been without benefit. There is another report of failure to relieve hemolysis by removing an ovarian cyst with later relief following splenectomy. Thus a possible synergistic effect of spleen and ovarian tumor is suggested in the cases reported by others. However, it is not possible to state that removal of the tumor alone might not have been effective in the cases in which this operation was preceded by splenectomy.

Two of the three tumors here reported were dermoid cysts; the classification of the other tumor was not stated. Broadly speaking, it is possible to regard many ovarian tumors as one-sided developments of teratomas, dermoid cysts being merely one variety. Hence our patient's tumor was possibly of the same type as described by the authors mentioned.

This can be considered an example of a symptomatic hemolytic anemia as has been reported[3] in leukemia, Hodgkin's disease, carcinomatosis and other conditions. Doubtless the anemia seen so frequently in association with various malignant tumors is often of this type. Failure to classify it as such is probably largely due to inadequate study of the blood. It seems futile to speculate on the possible relationships of her tumor and hemolytic anemia to her dermatomyositis and her anti-Rh agglutinins.

SPONTANEOUS RUPTURE OF THE SPLEEN IN MALARIA

FATAL CASE

CAPTAIN AARON KELLNER, CAPTAIN ELLIOTT HOCHSTEIN AND LIEUTENANT COLONEL A. J. B. TILLMAN
MEDICAL CORPS, ARMY OF THE UNITED STATES

A case report of spontaneous rupture of the spleen during a malarial paroxysm is presented to draw attention to this unusual complication of malaria. The incidence of splenic rupture in malaria is rare. Sporadic cases have been reported from the tropics[1] as complications of chronic malaria or of malignant tertian malaria (Plasmodium falciparum). This case is unusual in that it occurred in New England in a relapse of benign tertian malaria (Plasmodium vivax) which had been of relatively short duration.

REPORT OF CASE

A white man aged 28, a medical technician, was admitted to the A. A. F. Regional Station Hospital, Westover Field, at 4 p. m. on April 22, 1944 complaining of chills, fever and vomiting. His present illness began on April 19, three days prior to admission, with drowsiness, fever, chills and low backache, which the patient attributed to a recurrence of malaria and for which he took 3 grains (0.2 Gm.) of quinine. He was home on furlough at the time and did not think it necessary to seek medical care. The following day he felt better and was able to resume normal activity. On April 21, the day before admis-

From the Laboratory and Medical Services, A. A. F. Regional Station Hospital, Westover Field, Mass.

1. DeSaram, G. S. W., and Townsend, R. F.: Spontaneous Rupture of the Spleen in Malignant Tertian Malaria, Lancet 1: 584 (May 8) 1943.

sion, he suddenly had a chill and fever and he vomited several times and was brought to the hospital the following day.

This soldier had been stationed on islands in the South Pacific for sixteen months and had returned to the United States in June of 1943. While in the malarious districts he had taken atabrine daily as suppressive therapy and had not had an attack of clinical malaria. About two weeks after returning to this country and after discontinuing the atabrine therapy he had his first attack of malaria and was hospitalized for four weeks. At this time it was discovered that he was unable to tolerate atabrine in large doses. His second attack occurred three months later when he was hospitalized for two weeks. His third relapse was milder and followed in four months. This took place one month prior to his present illness, which was his fourth recurrence in a period of nine months. The past history and family history were essentially negative. He was born and spent his life in New England. There was no history of recent or old trauma to the abdomen or chest.

Physical examination on the afternoon of admission revealed that the patient was well developed and well nourished and did not appear acutely ill. The temperature was 99.8 F. rectally, the pulse rate 80 and the respiratory rate 20. The skin was of normal texture and had a yellowish tint consistent with previous atabrine therapy. The eyes, ears, nose and throat were normal. There was no nuchal rigidity. The thoracic cage was symmetrical, with no respiratory restriction. The lungs were clear to percussion and auscultation. The heart was not enlarged. The heart sounds were of good quality and there were no murmurs present. The abdomen was soft; the spleen was palpable 1 fingerbreadth below the left costal margin and was not tender; the liver was not felt. The external genitalia were normal. Rectal examination was negative. There was no cervical, axillary or inguinal adenopathy. The extremities were normal, with no evidence of arthritis or muscular weakness. Reflexes were physiologic.

Thick and thin blood smears made shortly after admission showed a small number of ring forms and trophozoites of Plasmodium vivax. The red blood cell count was 4.47 million; hemoglobin 88 per cent (Sahli); white blood cell count 6,500, with 69 per cent polymorphonuclears and 31 per cent lymphocytes. The urine was normal.

The patient did not receive any antimalarial therapy that evening. He had a very comfortable night. At 8:50 the following morning he had a shaking chill which was accompanied by vomiting. His temperature rose rapidly, reaching a peak of 106 F. in two hours, and then began to subside. The pulse rate was 110 to 120 and of good quality. He was seen by several members of the medical service, who thought his condition was satisfactory and saw no cause for alarm. At 11:30 a. m. he began to vomit profusely. Shortly thereafter he complained of numbness of his legs, severe epigastric pain and blindness. There was no pain referable to either shoulder. He then went into circulatory collapse, with a cold and clammy skin and an imperceptible pulse. Air hunger soon became evident. There was no rigidity of the abdomen noted. In spite of heroic therapeutic measures the patient died within thirty minutes. The diagnosis of a ruptured abdominal viscus was entertained only in retrospect, after the patient had died.

Autopsy was performed two hours after death. The peritoneal cavity was found to be filled with 2,500 cc. of fresh and for the most part unclotted blood. The source of the massive hemoperitoneum was a rupture of the spleen. The spleen weighed 400 Gm. and measured 15 by 13 by 4 cm. There was a transverse laceration through the capsule across the midportion of the spleen anteriorly. There were no adhesions between the capsule and the under surface of the diaphragm or any of the surrounding viscera. The capsule of the spleen had been dissected free from the underlying parenchyma, from which it was separated by a small amount of fresh soft blood clot. The capsule readily slipped back over the upper and lower poles of the spleen, completely decapsulating the organ. The spleen itself was of an unusually soft, mushy, almost diffluent consistency. There were several small stellate lacerations of the pulp at the lateral border of the spleen. The cut surface was reddish purple and contained large and prominent malpighian corpuscles. The pulp scraped readily. Sections of the spleen were cut with great difficulty, owing to the extremely soft character of the organ. The liver was not enlarged, and the brain showed no gross abnormalities. The only other findings at autopsy were an obliquely patent foramen ovale, cholelithiasis and old healed minimal apical tuberculosis.

Histologically the spleen and liver showed a considerable increase in reticuloendothelial cells, many of which contained small amounts of brown pigment. The spleen showed a relative decrease in the number of trabeculae, and the cells of the splenic pulp were widely spread apart. There was a small amount of hemosiderin in macrophages about a few of the blood vessels in the brain. No intact malarial parasites could be demonstrated on the sections, and there was no histologic evidence in any of the viscera of plugged or thrombosed capillaries.

COMMENT

The presence of a large number of American troops in regions of the world where malaria is hyperendemic has focused attention on this disease as a leading military and medical problem. The return of thousands of men to this country and their discharge into civilian life will make malaria a disease to be seriously considered in differential diagnosis, even in those parts of the country where malaria was previously rare or nonexistent. The preponderant number of cases of recurrent malaria that are seen in this country are due to Plasmodium vivax. It is worthy of note that malaria due to Plasmodium vivax, commonly referred to as "benign tertian" malaria, may give rise to serious and fatal complications.

Spontaneous rupture of the spleen is not a commonly encountered condition. In a recent review of the literature Zuckerman and Jacobi [2] cite 21 cases of spontaneous rupture of the normal spleen without a history of antecedent trauma. Spontaneous rupture of the diseased spleen is more common [3] and may occur in active cases of typhoid or malaria. It may also occur in any of the diseases causing splenomegaly, such as leukemia, Banti's syndrome or kala-azar. Spontaneous rupture of the spleen has been reported by Ziegler,[4] King [5] and Friesleben [6] in the acute phase of infectious mononucleosis. In the 3 cases which Ziegler reports there was one death; 2 patients were saved by surgical intervention.

Rupture of the spleen in malaria, while it has been reported, is nevertheless an uncommon complication. The increasing incidence of malaria in this country may bring an increase in the frequency of this disastrous complication. It is only by an awareness of its occurrence and an alertness on the part of medical personnel in recognizing and promptly initiating heroic surgical procedures that a fatal outcome can be averted.

The etiologic factors in spontaneous rupture of the spleen when no definite history of trauma can be elicited are speculative. The rupture may be due to minor trauma overlooked or forgotten by the patient. Other etiologic possibilities may be sudden increase in intra-abdominal pressure attendant on violent straining, coughing, sneezing or vomiting. An unrecognized source of trauma may be overzealous palpation of the abdomen during physical examination. The extremely soft mushy spleen that is encountered in acute malaria may be especially vulnerable to these minor stresses. Caution is therefore urged in palpating the abdomen and especially in palpating for the spleen in acute malaria.

The symptoms of acute splenic rupture are those due to irritation of the peritoneal surfaces by the extravasated blood and those due to blood loss. The first group of symptoms manifests itself by sudden pain in the epigastrium or left upper quadrant or by referred pain in the left shoulder. In the 21 cases reported by Zuckerman and Jacobi,[2] vomiting occurred in 12. It was a prominent feature in our case. The second group of symp-

6. Friesleben, M.: Splenectomy for Spontaneous Rupture, Deutsche Ztschr. f. Chir. 173: 45, 1922.

toms is due to acute massive blood loss with the familiar picture of circulatory collapse.

Diagnosis is made by an awareness of the possibility of rupture of the spleen in acute malaria, both malignant and benign, and the immediate recognition of the symptoms. The treatment is immediate splenectomy.

SUMMARY

A patient with a recurrence of Plasmodium vivax malaria sustained an apparently spontaneous rupture of the spleen during a paroxysm and went into collapse, dying in a short while from exsanguination into the peritoneal cavity. The spleen at autopsy was extremely soft and mushy and it is of more than academic interest to know whether the trauma of physical examination or of violent coughing or vomiting may have been a factor in producing the rupture. The degree of parasitemia was very slight and there was no histologic evidence of plugged or thrombosed capillaries in any of the viscera.

ADDENDUM

Since the preparation of the foregoing case report we have been informed by the director of the Army Institute of Pathology that there are 3 similar cases in its files. In 2 of these cases the diagnosis was made post mortem. In the third case the diagnosis was made during life and a splenectomy was performed, resulting in the recovery of the patient.

Council on Industrial Health

THE EFFECT OF FLUORESCENT LIGHT ON VISION

The following statement, submitted to the Council on Industrial Health by the Joint Committee on Industrial Ophthalmology representing the Section on Ophthalmology of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology, has been approved for publication.

C. M. PETERSON, M.D., *Secretary.*

Fluorescent lighting has been regarded by physicians and others as possessing harmful qualities not found in other forms of artificial illumination or in daylight. Both the ultraviolet and infra-red components have been suspected. The Joint Committee on Industrial Ophthalmology, after consultation with specialists in the production and use of light, holds the following opinion:

1. The ultraviolet energy from clear blue summer skylight is three to four times as great per footcandle as fluorescent light.

2. Light from fluorescent lamps resembles daylight more closely than that from tungsten-filament lamps. This color resemblance to daylight is a desirable quality.

3. Infra-red energy found in fluorescent lighting as now manufactured produces no known physiologic effect except that due to heating. Fluorescent light generates less heat per candlepower than tungsten lamps.

4. Glare occurs in any system of lighting. Its solution rests with illuminating engineers.

5. Individual differences occur in the level of illumination (footcandles) required to provide a satisfactory degree of visual efficiency and eye comfort. Twenty footcandles is essential for such critical tasks as reading. Higher levels of illumination are desirable for prolonged seeing, for discrimination of fine details and where low contrast prevails. These standards can be readily maintained in working places through use of properly installed fluorescent lighting.

6. Excessive light may produce symptoms of eyestrain in susceptible individuals regardless of source. Constitutional factors should be corrected as well as the amount and kind of light.

7. Noticeable flicker is largely eliminated in modern fluorescent installations.

SUMMARY

Fluorescent light is not harmful to vision. It should not cause eyestrain if properly installed and used.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

NEO-SYNEPHRINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1944, p. 284).

The following additional dosage form has been accepted:

FREDERICK STEARNS & COMPANY, DETROIT

Solution Neo-Synephrine Hydrochloride, 1 per cent: 1 cc. ampuls and 5 cc. vials. Neo-synephrine hydrochloride 1 per cent, sodium bisulfite 0.10 per cent and sodium chloride 0.6 per cent.

MENADIONE (See New and Nonofficial Remedies, 1944, p. 638).

The following dosage forms have been accepted:

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Tablets Menadione: 1 mg. and 2 mg.

Solution Menadione (in corn oil) 2 mg. per 2 cc.: 2 cc. ampules. Each cubic centimeter contains 1 mg. menadione.

CHLOROAZODIN (See New and Nonofficial Remedies, 1944, p. 125).

The following additional dosage form has been accepted:

WALLACE & TIERNAN PRODUCTS, INC., BELLEVILLE, N. J.

Surface Active Saline Mixture of Azochloramid: 4.7 Gm. envelops. Each envelop containing azochloramid 0.14 Gm., sodium tetradecyl sulfate 0.47 Gm. and buffered saline mixture 4.09 Gm. for the preparation of 473 cc. of isotonic solution.

PENICILLIN (See Supplement to New and Nonofficial Remedies, 1944, p. 18).

The following dosage forms have been accepted:

HEYDEN CHEMICAL CORPORATION, NEW YORK

Penicillin Calcium Salt: 100,000 Oxford unit or 200,000 Oxford unit ampuls or vials.

MCNEIL LABORATORIES, INC., PHILADELPHIA

Penicillin Sodium: 100,000 Oxford units in 20 cc. vials.

CARROLL DUNHAM SMITH PHARMACAL COMPANY, ORANGE, N. J.

Penicillin Sodium Salt: 20 cc. vial containing 100,000 Oxford units, packaged with a 20 cc. vial of isotonic solution of sodium chloride.

THE WARREN-TEED PRODUCTS COMPANY, COLUMBUS, OHIO

Penicillin Sodium Salt: 100,000 Oxford unit vials.

COMMERCIAL SOLVENTS CORPORATION, NEW YORK

Penicillin Sodium Salt: 100,000 Oxford unit vials.

Penicillin Calcium Salt: 100,000 Oxford unit vials.

SULFADIAZINE (See New and Nonofficial Remedies, 1944, p. 178).

The following dosage form has been accepted:

WYETH INC., PHILADELPHIA

Tablets Sulfadiazine: 0.5 Gm.

CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies, 1944, p. 339).

The following dosage form has been accepted:

CONTRA CREME AND DIAPHRAGM CO., SEVERNA PARK, MD.

U. S. trademark 355,838.

Contra Creme: A stearic acid cream having a p_H of 7.3, packaged from the formula:

Phenylmercuric acetate	0.06%
Triethanolamine	0.06
Glycerin	2.5
Glycol monostearate	3.5
Stearic acid	12.0
Distilled water to make	100.00

Dosage.—An applicator which is included in the package is attached to the tube and half filled with the creme. The contents of the applicator are then inserted carefully into the vagina.

SATURDAY, AUGUST 25, 1945

THE WAR ENDS

Suddenly the war ended. Men and women were mostly jubilant; some sorrowful, some even apathetic, with a feeling of exhaustion. The control over gasoline was removed; almost immediately roads were overwhelmed with traffic. Along the curbs stood motor cars with tires that burst or springs that cracked or engines that stuck—reminders that motoring will have to await a return to normalcy. So also with human beings—the stresses and strains of the war reveal themselves in a variety of inadequacies—combat neurosis was not limited to the military services.

The end of the war in Europe brought to the headquarters of the American Medical Association a veritable deluge of letters from medical officers urging that steps be taken at once to insure their instant separation from the service. Occasionally a wife wrote saying "You got my husband into this; now you get him out!" The letter from five medical officers in England, published in THE JOURNAL, stimulated groups here and there in various military installations to send similar communications. Several were received signed by more than a score of medical officers ranging from lieutenant colonels to lieutenants. Now the war is over—and the planning that contemplated a war ended in Europe must be done over for a war ended also in the Pacific.

The wounded are still coming home. For maximum recovery the armed forces carry the wounded to centers where they receive the attention of specialists. The Army Medical Department has already indicated that replacements for what the Army calls "scarce specialists" are not available.

War's end finds many, many questions of vital interest to American medicine as yet unsettled. The supply of medical and premedical students; the disposal of Army and Navy surplus medical supplies; a proper organization and system for medical services to veterans; the maintenance of intensified, coordinated research; the redistribution and relocation of returning medical officers; the provision of adequate numbers of residencies in the specialties; the development of medical care in the areas of occupation; the reestablishment of interchange of medical information throughout the world—these are but a few of the many problems that demand prompt consideration, careful planning, possible solution.

Much proposed legislation affecting medical care in postwar America is already before the Congress. New measures tremble in the minds of Senators and Congressmen and in the thoughts of personnel in governmental agencies who seek new fields to conquer. The Office of Defense Transportation relaxed to the extent of permitting groups of 150 individuals to attend conventions. Such relaxation does not, however, permit the assembling of the House of Delegates of the American Medical Association. Yet an early meeting of this body is desirable so that the policies of the Association regarding many problems may be established through its democratically selected official group.

These are truly, even as in war, times that try men's souls. Scientifically minded physicians will realize that now, even as in war, haste must be made slowly. With sympathetic understanding, with the determination to see the job through to its fortunately happy ending, with the resolve to sink individual desires just a little more for the common good, let us practice more forbearance, so that our world may be that much sooner again a well ordered civilization.

DIABETIC NEUROPATHY

Although pathologic conditions of the peripheral nerves have long been recognized, little unanimity prevails concerning the etiology and symptomatology of such conditions. So-called diabetic neuropathy has been considered by some to be the result of degenerative changes resulting from the disease of the peripheral arteries, by others the result of nutritional deficiency resulting from dietary modifications. The subject has been investigated anew by Rundles [1] in the medical wards of the University Hospital of Ann Arbor, Mich. Among some 3,000 diabetic patients treated since 1936, the diagnosis of diabetic neuropathy was made in 125. Most diabetic patients who develop organic disease of the peripheral nerves have apparently had antecedent periods of grossly neglected or poorly managed treatment. The disordered metabolism of diabetes seems to be the etiologic factor in this complication. Severe polyneuropathy was precipitated, sometimes acutely, after periods of diabetic neglect, by common infections, surgical procedures and other events capable of aggravating the severity of diabetes. Not only may the

1. Rundles, R. W.: Diabetic Neuropathy: General Review with Report of 125 Cases, Medicine 24: 111 (May) 1945.

peripheral motor and sensory neurons be involved, according to Rundles, but also spinal nerve roots, autonomic pathways concerned with temperature regulation, postural blood pressure adjustment, vasomotor control and intestinal and bladder function. He reports that he has not seen a patient in whom diabetic neuropathy actually preceded the appearance of diabetes mellitus. This observation is in agreement with that of Joslin and Root, who state that the symptoms of diabetic neuropathy always start during a time of uncontrolled diabetes.

Rundles finds that diabetic neuropathy tends to occur in patients with mild diabetes, many of whom have had neither diabetic acidosis nor coma, as well as in those with more severe diabetes. In 25 of his cases there had been no diabetic treatment at all before the hospital admission. Of the remaining patients who had some treatment, every one seemed to have received only what would be called poor treatment. Liver enlargement was found in 38 patients with diabetic neuropathy, excluding those with cardiac, biliary tract and other recognized hepatic disease. Among early symptoms were muscular cramps, aching and muscular weakness, especially of the legs, and these symptoms were characteristically made worse on exposure to cold and at night. The lower extremities were affected more severely, almost without exception. The peroneal nerve was more vulnerable than the tibial, the ulnar more vulnerable than the radial or median. Occasionally symptoms occurred predominantly in the pudendal, femoral or intercostal nerve areas, or asymmetrical areas in the extremities. With uncontrolled diabetes the tendency was toward increasing severity and persistence of symptoms. Events which seemed to produce or precipitate neuritic changes in this group were severe upper respiratory infections, influenza, pneumonia, pyogenic infections, toxic hyperthyroidism, diabetic acidosis, diabetic coma and surgical operations. Diminished or absent tendon reflexes constituted the commonest neurologic abnormality. The cutaneous sensibilities were blunted peripherally in about half of the patients. Pronounced muscle tenderness was present in 46 cases. The vibratory sense at the ankles was diminished in 37 patients and absent in 20. Complete foot drop was present in 10 cases. The abnormal pupils were in most instances miotic, reacting sluggishly to light, better on accommodation. Irregular and unequal pupils were observed. Thirty-nine spinal fluid examinations were made in 31 patients. Ten fluids were normal, while 13 had excess total protein ranging from 48 to 80 mg. per hundred cubic centimeters. Disturbed gastrointestinal function appeared to be a common accompaniment of diabetic neuropathy and one which the author, in view of the other evidence of disturbed autonomic nerve function, as well as the high incidence in the same patients of genitourinary and sphincter abnormality, considered the result of autonomic nerve disease.

Thirty-two of the patients in this study had genitourinary and sphincter disturbances. Complete lack of sexual potency was recorded in 19 patients, and this often preceded any other symptom of peripheral nerve disorder. Eighteen patients were found to have an atonic type of bladder paralysis. Cystometric examinations in 13 of these showed impaired or absent sense of feeling, low expulsive force and an increased bladder capacity. The sphincter disturbances appeared to be the result of involvement of the pudendal nerve. The bladder paralysis of diabetic neuropathy is an atonic neurogenic paralysis similar to that seen in tabes dorsalis, pernicious anemia with peripheral nerve and posterior column disease and alcoholic neuropathy.

Some of the patients with diabetic neuropathy exhibited unusual degrees of peripheral sympathetic nerve damage, as revealed by sweating deficiencies, loss of vasomotor and pilomotor control, dependent edema and certain types of skin alteration. This type of edema is presumably due to involvement of the vasomotor nerves. Defective orthostatic regulation of the blood pressure was found in 8 of the patients. The blood pressure in the supine position was usually normal, but the systolic and, to a lesser degree, the diastolic pressure declined precipitously on standing, causing faintness, dizziness and syncope.

The successful treatment of diabetic neuropathy requires expert diabetic management. Rundles found that administration of insulin was the most effective means in the control of this complication. He insists that it should be given at least for the duration of the active neuritic disease. Benefit was not observed from the addition of vitamins, and in particular of thiamine. This observation lends support to the opinion of Meiklejohn [2] as to the role of thiamine in the causation of polyneuritis. A poorly understood and disturbing phenomenon encountered in the treatment of diabetic patients with associated neuropathy is the acute intensification of the neuritic disease which sometimes occurs shortly after control of the diabetes is undertaken. Neuritic disease may also appear for the first time in those with a history of prolonged diabetic neglect a few weeks after treatment is begun.

This study points out the association of diabetic neuropathy with chronic unregulated diabetes and suggests a metabolic cause, the nature of which, however, has not thus far been elucidated. The author emphasizes that diabetic neuropathy, as well as retinopathy and hepatomegaly in their early stages, are reversible changes, provided they are recognized early and are properly treated.

THE CELLULAR SOURCES OF ANTIBODIES

The production of antibodies in lymph nodes was first demonstrated by McMaster and Hudack[1] by grinding lymph nodes of 20 to 30 mice with sand and determining antibody titers in the extract. The observations of McMaster and Hudack were confirmed by Ehrich and Harris[2] by comparing antibody titers in the pad of the hind foot of the rabbit (which was the site of injection of antigen), the lymph contained in the peripheral lymph vessels, the popliteal lymph node (the only node regional to the site of injection), the efferent lymph and the blood serum.

As to the cells involved in antibody formation, Ehrich and Harris first showed that the cellular response in the lymph node during antibody production was chiefly a lymphocytic one, and the simultaneous rise of cells in the efferent lymph from about 18,000 per cubic millimeter of lymph to 60,000 or more was almost entirely lymphocytic (more than 99 per cent of all cells were lymphocytes). Following this observation, Harris, Grimm, Mertens and Ehrich[3] demonstrated that, during antibody formation in the lymph node, antibodies were contained largely in the lymphocytes, the supernatant lymph plasma containing only a fraction of the antibodies present in the lymph.

In accord with the observations of Ehrich and his associates, Dougherty, Chase and White[4] noted that after repeated intra-abdominal injections with sheep erythrocytes the cells from pools of the minced inguinal, axillary, cervical and mesenteric lymph nodes and thymus contained about double as much antibody as the serum of these animals. Recently White and Dougherty[5] and Kass[6] showed that cells from pools of minced lymph nodes also contained normal gamma globulin. Though these cells probably consisted mostly of lymphocytes, a considerable number of monocytes and probably granulocytes must have been present also. Their contention that the antibodies and gamma globulin were contained in lymphocytes may be regarded as valid, however, in the light of the earlier work of Harris, Grimm, Mertens and Ehrich, whose method furnished them with an almost pure strain of lymphocytes (more than 99 per cent of all cells were lymphocytes).

Dougherty, Chase and White came to the conclusion that "antibodies are concentrated in lymphocytes," "the lymphocyte functioning as a carrier of antibody," and that "the active production of antibodies by lymphocytes has not been established." However, Ehrich and Harris[7] pointed out that the reticuloendothelial theory of antibody formation was not really supported by evidence, but their own observations as well as all the older facts fitted better into a lymphocytic theory of antibody formation, in which possibly the granulocyte as well as the macrophage also played an essential role.

Whatever conclusion will finally prevail, it may now be regarded as established that the lymphocyte is not merely an undifferentiated hemocytoblast but has something to do with gamma globulin and antibodies. It either stores or produces these globulins. The evidence available at present favors the latter theory.

Current Comment

THE AUTOMOBILE NUMBER—1906

On April 21, 1906 THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION—circulation 45,000 copies—issued a special number called the Automobile Number. A facsimile, prepared by the Advertising Department of the American Medical Association, is now being circulated to persons interested in the promotion of motor cars and accessories. The facsimile will take many an American physician back to the early days of his trials and tribulations with the motor cars of a vintage of three decades ago. Some of the amazing articles in this issue bear such interesting titles as "The Auto Too Much Trouble to Keep in Order," by F. A. Swezey, M.D., Wakonda, S. D.; "Synopsis of a Chicago Experience," by Arthur R. Edwards, M.D., Chicago; "Four Years' Success with a Steam Car," by J. G. Henry, M.D., Winchendon, Mass.; "Tires and Roads Are the Chief Automobile Troubles," by William Allen Pusey, M.D., Chicago; "Statistics on Auto, Horse and Pulse," by Charles P. Sylvester, M.D., Dorchester, Mass. In an interesting article entitled "The Physician Who Should Not Purchase an Auto" W. W. Beveridge, M.D., Asbury Park, N. J., asserts that the careless physician cannot run an auto. There are some striking comparisons between the use of the automobile and of the horse in medical practice. Reproductions of the advertisements of that day add to the interest of the text. The illustrations reveal not only the strange motor cars of 1906 but some demonstrations of what was considered a natty costume for a physician of that day. A copy of this interesting reproduction is available at 25 cents to those physicians who will address their request to the American Medical Association.

NUTRITION OF SCHOOL CHILDREN

Discussion of the part played by nutritional disorders in the rejections of young men for military service directs attention again to the importance of proper nutrition during the period of growth. Too little thought has been devoted in the past to this aspect of child care. The need for improvement is emphasized by recent surveys made on the dietary habits and nutritional status of children in this country. The Florida State Board of Health [1] reports a survey conducted early this year in various counties throughout the state. Over 2,000 children of rural and urban communities from grades 1 through 12 were examined for the presence of specific signs of nutritional deficiencies and anemia. The incidence of such findings was disconcertingly high, the more so because they occur in an area where sunshine and fresh produce should be plentiful. For example, in some sections well over 50 per cent of the children showed at least slight signs of rickets and also indications of vitamin C deficiency. In one isolated rural area 50 per cent of those examined had gum signs indicative of a lack of vitamin C. The frequency with which signs suggestive of other deficiency states such as the roughened skin or granulated eyelids of vitamin A deficiency and the angular stomatitis of riboflavin need was as high as 64 per cent for vitamin A and 85 per cent in the case of riboflavin in some of the nutritionally poorest groups. Anemia was not encountered as frequently in these children as the more specific entities, although the hemoglobin levels of Negro children were found to be generally lower than those of the white children in the same area. A concurrent dietary survey was made to determine the types of foods eaten by Florida school children. The information secured by this means corroborated the observations made on the children themselves. Not only were many valuable types of foods such as colored vegetables, citrus fruits and milk missing from the diet lists of a goodly proportion of the children questioned, but the reports show also that many children go without one meal during the day, usually the breakfast, or eat a breakfast which is totally inadequate. Facts of similar import are revealed from the national survey of children's diets made by the *Ladies Home Journal* as reported in that publication.[2] Here again it was found that a distressingly high percentage of children from all types of homes receive meals which are poorly selected. These studies show that many children are not receiving their share of the benefits of this country's resources in the way of good foods for the maintenance of good nutrition. Scientific investigation has demonstrated the dietary needs of children and adults for optimal health. Invariably the foods can be made available if the proper knowledge and interest are applied. The recent authorization of Congress for the expenditure of $50,000,000 by the Department of Agriculture to continue school lunch programs for the coming year will no doubt assist local groups to provide adequate lunches for children in all schools participating. The extent of the problem calls for more and more communities to avail themselves of all means of improving the nutrition of their children if the health and efficiency of future generations are to be safeguarded.

OXIDATIVE CAPACITY OF THE BODY

Determination of the levels of pyruvic and lactic acids in the blood has been of use in studies related to carbohydrate metabolism and thiamine deficiency. The applicability of this procedure has been extended by the work of Friedemann and his associates,[1] in which it was shown that these tests can be made under more normal conditions of activity than the fasting state. The effects of such factors as food, activity and anoxia were tested. Hourly blood samples were taken on 10 subjects eating regular meals and performing their tasks of office and laboratory work. The pyruvic and lactic levels rose to a maximum from one to two hours after an average meal and returned to the original level in three to four hours, roughly paralleling the blood sugar level, but the lactic-pyruvic ratio remained essentially constant throughout. Further observations on persons engaged in laboratory and office work and on medical students indicated that light activity does not materially affect the lactic-pyruvic ratio, although fluctuations from the mean were found in the period immediately after meals as well as later. The arithmetical mean of this ratio for these active subjects was nearly identical with that found in 16 hospital patients confined to bed over an extended period, in spite of their differences in activity. In studies made on a trained runner the lactic-pyruvic ratio after walking a mile rapidly closely approximated that observed in sedentary workers, while the ratio rose sharply with the greater demands for oxygen incident to increasing the speed of running the mile. Of particular interest are the values obtained under simulated conditions of high altitude. Below 15,000 feet the ratio of these acids remains unchanged, whereas above this altitude the lactic acid content of the blood rises to produce an increase in the lactic-pyruvic ratio. That this is related to the anoxia produced was demonstrated by the administration of oxygen or return to 10,000 feet altitude, in which case the ratio returned to normal. This evidence of disruption in the oxidative processes of the body at altitudes previously known to be incompatible with life now offers a physiologic explanation for this well established fact. These observations made under varying conditions of oxygen requirement support the author's [2] contention that the lactic-pyruvic ratio serves as a measure of the relative oxidative conditions of the body. Further application of this procedure may be expected to provide information on such controversial questions related to oxidative capacity as physical fitness and the use or abuse of rest as a therapeutic agent.

MEDICINE AND THE WAR

ARMY

CIVILIAN SPONSORED ARMY TECHNICAL UNITS TO BE CONTINUED

In a recent announcement by the War Department, it was stated that army technical units sponsored and manned by civilian institutions and organizations will not be disbanded after the war. The War Department granted authority early in the war to numerous civilian institutions and organizations to sponsor military units which required personnel with a high degree of professional or specialized training. In general, this authority was confined to the fields of medicine, motor and rail transportation, motion pictures, motor maintenance and communications.

Following is a list of the medical units now serving in the Army of the United States which will go on a reserve status when the Army is demobilized after the war:

2d Evacuation Hospital—St. Luke's Hospital, New York.
7th Evacuation Hospital—New York Post-Graduate Hospital, New York.
9th Evacuation Hospital—the Roosevelt Hospital, New York.
12th Evacuation Hospital—Lenox Hill Hospital, New York.
18th Evacuation Hospital (inactive)—Methodist Hospital, Indianapolis.
22d Evacuation Hospital (inactive)—Milwaukee County Hospital, Wauwatosa, Wis.
25th Evacuation Hospital—West Suburban Hospital, Oak Park, Ill.
27th Evacuation Hospital—University of Illinois, Urbana, Ill.
35th Evacuation Hospital—Gallinger Municipal Hospital, Washington, D. C.
38th Evacuation Hospital—Charlotte Memorial Hospital, Charlotte, N. C.
45th Evacuation Hospital—West Suburban Hospital, Oak Park, Ill.
46th Evacuation Hospital (inactive)—University of Georgia, Augusta.
48th Evacuation Hospital—Rhode Island Hospital, Providence.
49th Evacuation Hospital (inactive)—Starling Loving, University of Ohio, Columbus.
50th Evacuation Hospital (inactive)—Worcester City Hospital, Worcester, Mass.
55th Evacuation Hospital (inactive)—Anker Hospital, St. Paul.
56th Evacuation Hospital—Baylor University Medical School, Dallas, Texas.
73rd Evacuation Hospital—Los Angeles County General Hospital, Los Angeles.
77th Evacuation Hospital—University of Kansas Hospital, Kansas City, Kan.

64TH MILITARY GENERAL HOSPITAL CITED

The Meritorious Service Unit Plaque was recently presented to the 64th Military General Hospital, which is sponsored by the Louisiana State University School of Medicine. Its medical officers are members of the faculty and alumni of the school. The 64th General Hospital was cited "for superior performance of exceptionally difficult tasks and outstanding devotion to duty in the Peninsular Base Section for the period Aug. 1, 1944 to Oct. 1, 1944. This medical unit was the first hospital in line of evacuation of casualties from fighting in the Arno River sector. This hospital quickly adapted itself to field hospital technics. From Aug. 1, 1944 to Oct. 1, 1944 the professional service of the hospital functioned on a twenty-four hour basis. The superior care of medical patients and battle casualties was consistent with the unselfish ideals of the medical service of the United States Army. With rigid discipline and full knowledge of and devotion to its mission the 64th General Hospital upheld the highest traditions of the United States and of the Allied Nations."

MEDICAL MEETING HELD IN SICILY

A medical meeting was held at the Reale Accademia Peloritana, Messina, Sicily, on June 14 at which many papers were read and discussed and new discoveries announced. Dr. Domenico Pisani is the head of the Accademia.

HOLD MEETING AT U. S. ARMY GENERAL HOSPITAL, CAMP PICKETT

Army medical men recently held a get-together at the U. S. Army General Hospital at Camp Pickett, Va., with a trio of prominent civilian medical specialists and exchanged views on topics ranging from streamlined methods of treating complicated fractures and tropical diseases through the postwar medical world picture. Dr. Guy Leadbetter, president-elect of the American Academy of Orthopedic Surgeons and associate professor of surgery at George Washington University, Washington, D. C., demonstrated a new technic he has developed for correcting ununited fractures of the hip bone by operating on a soldier patient. Besides Dr. Leadbetter, the visiting medical men were Dr. William Harvey Perkins, dean of the Jefferson Medical College of Philadelphia, Dr. Lewis C. Scheffey, professor of gynecology at the same institution, and Col. Walter D. Wise, surgeon consultant of the Third Service Command.

Major Vladimir G. Urse, chief of the neuropsychiatric section of the General Hospital at Camp Pickett and one of several army physicians participating in the round table discussion, stressed the increasing importance of further study of the relationship between stomach disorders and psychoneuroses. The individual must be considered as a total organic being, inclusive of his situation, in diagnosis, he said.

CHIEF ADMINISTRATIVE OFFICER FOR THE OFFICE OF THE SURGEON GENERAL CITED

Col. Joseph Carmack, formerly of San Antonio, Texas, was recently awarded the Cross of Knight Commander, Order of the Crown of Italy, in recognition of his meritorious services during the Italian campaign. In the official citation Colonel Carmack, chief administrative officer for the Office of the Surgeon General, ETOUSA, was praised for his long and meritorious service in the campaign which saw the liberation of Italy.

BRAZILIAN AIR SURGEON VISITS SCHOOL OF AVIATION MEDICINE

Brigadeiro do Ar Angelo Godinho dos Santos, Air Surgeon of Brazil, and his aides, 1st Lieut. Fernando dos Santos and 2d Lieut. Jose dos Santos, visited the AAF School of Aviation Medicine, Randolph Field, Texas, during a three week tour of army and navy medical installations throughout the United States. Accompanying Brigadeiro Godinho are Brig. Gen. G. Reinartz, commandant of the School of Aviation Medicine, Lieut. Col. William A. Glasier, from the office of the Air Surgeon, and Major Andrew Masset, interpreter.

MAJOR TRYGVE GUNDERSEN SUCCEEDS COLONEL DERRICK T. VAIL

Major Trygve Gundersen, formerly consultant in ophthalmology, Mediterranean Theater of Operations, and ophthalmologist of the Sixth General Hospital, was recently assigned to the Office of the Surgeon General as chief, ophthalmology branch, Surgical Consultants Division. He replaces Col. Derrick T. Vail, who will become professor of ophthalmology and head of the department of ophthalmology, Northwestern University, Chicago.

THE EMERGENCY MEDICAL CARE OF ARMY PERSONNEL

Procedure to Be Followed by Civilian Physicians and Hospitals

Army personnel spend various lengths of time on leave or furlough at their respective homes, some of whom no doubt will require medical attention during this period. When possible, such personnel should be referred to the nearest federal medical installation for care and treatment. If the condition of the patient is such that immediate treatment or hospitalization is necessary, civilian medical attendance is authorized at public expense under existing regulations. This does not apply to Army personnel who are absent without authorized leave or to those who obtain elective medical treatment in civilian hospitals or by civilian physicians.

Service Command Surgeons

Location	*Component States*
Service Command Surgeon Headquarters First Service Command 808 Commonwealth Avenue Boston 15	Maine New Hampshire Vermont Massachusetts Rhode Island Connecticut
Service Command Surgeon Headquarters Second Service Command Governors Island New York 4	Delaware New Jersey New York
Service Command Surgeon Headquarters Third Service Command U. S. Post Office and Court House Baltimore	Maryland Pennsylvania Virginia
Service Command Surgeon Headquarters Fourth Service Command Post Office Building Atlanta 3, Ga.	North Carolina South Carolina Georgia Florida Alabama Tennessee Mississippi
Service Command Surgeon Headquarters Fifth Service Command Fort Hayes Columbus 18, Ohio	Ohio West Virginia Indiana Kentucky
Service Command Surgeon Headquarters Sixth Service Command Civic Opera Building 20 North Wacker Drive Chicago 6	Illinois Michigan Wisconsin
Service Command Surgeon Headquarters Seventh Service Command New Federal Building Fifteenth and Dodge Streets Omaha 2	Missouri Kansas Iowa Nebraska Minnesota North Dakota South Dakota Wyoming Colorado
Service Command Surgeon Headquarters Eighth Service Command Santa Fe Building Dallas 2, Texas	Texas Oklahoma Arkansas New Mexico Louisiana
Service Command Surgeon Headquarters Ninth Service Command Fort Douglas, Utah	Washington Oregon Idaho Montana Utah Nevada California Arizona

In case of emergency treatment or hospitalization, the individual or his attending physician should notify the appropriate service command surgeon as determined by the accompanying tabulation and give the following information:

Full name.
Military rank.
Army serial number.
Military address, including organization and home station (orders in possession of military personnel will give this information).
Diagnosis.
Estimated duration of treatment and approximate date when patient's condition will permit transfer to an Army hospital if hospitalization is required.

All bills for medical treatment or hospitalization will be submitted to the appropriate service command surgeon and must show the soldier's name, rank, serial number, organization and home station.

The accompanying tabulation indicates the appropriate service command surgeon for reporting medical care of Army personnel and submitting bills for payment. For either purpose the location of the hospital or the physician rendering the care determines the appropriate service command surgeon. In some instances it will be necessary for the service command surgeon to forward the bills to another command for payment.

ARMY AWARDS AND COMMENDATIONS

Major General Morrison C. Stayer

Major Gen. Morrison C. Stayer, formerly of Carlisle, Pa., was recently awarded the Oak Leaf Cluster to the Distinguished Service Medal in recognition of his achievements as chief of the U. S. Army surgeon in the Mediterranean Theater of Operations. The citation accompanying the award read "for exceptionally meritorious and distinguished service in a position of great responsibility in the Mediterranean Theater of Operations during the period March 3, 1944 to May 31, 1945. Charged with safeguarding the health and lives of American troops in the battlefields of Italy and southern France and in areas notorious for the prevalence of malignant and exotic diseases, General Stayer as theater surgeon prompted the medical services under his control to achieve a record which is generally regarded as a superior standard of efficiency. Under his direct supervision many important contributions to military medicine were advanced by installations located throughout a widely dispersed area. General Stayer held to the concept that mere saving of life was not enough and that surgery and wound management demanded complete recovery without disability or disfigurement, requiring the fullest utilization of highly developed methods and technics. His brilliant professional attainments, untiring energy and devotion to the welfare of the officers and men of the Army of the United States are in keeping with the highest traditions of the military service." Dr. Stayer graduated from Jefferson Medical College of Philadelphia in 1906 and was commissioned in the regular Army in 1908.

Captain Lawrence J. Caruso

Six military awards and citations have been awarded to Capt. Lawrence J. Caruso, formerly of Brooklyn. The Silver Star was awarded to him for gallantry in action against the enemy in the vicinity of St. Laurent-sur-Mer, Normandy. He voluntarily remained under intense enemy fire administering first aid and directing the evacuation of casualties. He assisted in the removal of injured soldiers from mine fields and succeeded in removing them to safety despite his own injuries, for which he was awarded the Purple Heart.

In August 1944 he received an Oak Leaf Cluster to his Silver Star by courageously entering an area receiving severe bombardment by enemy aircraft, administering first aid and directing the evacuation of casualties.

The Bronze Star was awarded to him for meritorious achievement in connection with military operations in the summer of 1944.

A Certificate of Merit was awarded in March 1945 for heroism in entering a burning building and extinguishing a fire which was threatening his men as well as the destruction of a large quantity of medical supplies.

He was recently awarded a second Oak Leaf Cluster for other meritorious service.

Dr. Caruso graduated from the Long Island College of Medicine, Brooklyn, in 1940 and entered the service June 20, 1942.

Captain Robert E. Vorisek

Capt. Robert E. Vorisek, formerly of New York, was recently awarded the Silver Star for gallantry in action at Colasion Point, Leyte. It is reported that with magnificent courage and determination Captain Vorisek exposed himself to flying shell fragments to administer medical attention to a number of casualties during intense enemy artillery shelling. When the order was given to evacuate the area, Captain Vorisek remained until all casualties had been treated and removed to a safer area. Dr. Vorisek graduated from the Long Island College of Medicine, Brooklyn, in 1941 and entered the service Dec. 30, 1942.

NAVY

INTERNSHIPS AND NAVY V-12 MEDICAL SCHOOL GRADUATES

Navy V-12 Bulletin 317, issued by the Bureau of Naval Personnel, describes the procedures currently in effect regarding internships for Navy V-12 medical students.

Students may elect to apply for internships either in naval hospitals (if 21 years of age or over) or in civilian institutions. In either case they will be appointed to the rank of Lieutenant (junior grade) MC or MC(S), U. S. Naval Reserve.

Students desiring assignment to a naval hospital should make application to the Bureau of Medicine and Surgery via their commanding officers after completion of their junior year. Candidates will receive official notification via their commanding officers as to their acceptance approximately six weeks from the date of receipt of application. In any case applications must be made at least sixty days prior to graduation. Commissions as well as active duty orders to a naval hospital will be transmitted to the student through his commanding officer on graduation.

Graduates who are not given time to take state board examinations prior to reporting for active duty at a naval hospital will, at the appropriate time after reporting, submit a request to the commanding officer for such leave as may be necessary to participate.

In view of the acute shortage of medical officers in the Navy and the Naval Reserve, it is the desire of the Bureau of Medicine and Surgery that every effort be made to encourage V-12 medical students to apply for intern training in naval hospitals.

Students electing to serve civilian internships or not selected for naval internships are advised to make every effort to contract for rotating internships, to commence within thirty days of graduation.

At least sixty days before graduation date the commanding officers of Navy V-12 units at medical schools submit lists of senior V-12 medical students scheduled to graduate indicating applicants who have been selected for intern training in naval hospitals and those who are committed to civilian internships.

LIFE SAVING FACILITIES IN PACIFIC

Rear Admiral Richard H. Laning (MC), U.S.N., inspector of Medical Department Activities, Pacific Ocean Areas, recently reported to Rear Admiral William J. C. Agnew (MC), U.S.N., acting chief of the Bureau of Medicine and Surgery, Washington, D. C., that the life saving facilities in the Pacific are at their peak in preparation for developments against the enemy. Boding well for future naval and amphibious operations, said Rear Admiral Laning, are improvements made in air evacuation of casualties, shipment by air of whole blood, deployment of newly added hospital ships, construction of additional fleet and base hospitals in forward areas and gains which have been achieved in prevention and control of communicable diseases.

NEW OCCUPATIONAL THERAPY BUILDING

A new occupational therapy building was recently opened at the National Naval Medical Center, Bethesda, Md., with a daily capacity of 300 patients in the fourteen workshops. A staff of 15 is under the direction of Lieut. (jg) M. S. Vetting (W) U.S.N.R., with Lieut. Comdr. H. S. Etter (MC), U.S.N.R., having general supervision. Dr. Etter is rehabilitation officer of the Naval Hospital.

COMMANDS UNITED STATES NAVAL HOSPITAL AT ST. ALBANS

Capt. Edwin D. McMorries (MC), U.S.N., recently took command of the United States Naval Hospital at St. Albans, Queens, L. I., N. Y. Capt. Lester L. Pratt (MC), U.S.N., who had been medical officer in command of the hospital since its inception in February 1943, will leave to become district medical officer of the Thirteenth Naval District, with headquarters in Seattle.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Henrik W. Szylejko

The Navy and Marine Corps Medal was recently awarded to Lieut. Henrik W. Szylejko, formerly of Philadelphia. The citation read "For heroism while serving as senior medical officer of the United States Landing Ship Tank 496 during the invasion of France from June 6, 1944 to June 13, 1944. When his ship was damaged by enemy action on the night of the 11th of June Lieutenant (jg) Szylejko was knocked unconscious by the terrific concussion. On regaining consciousness he carried the unconscious form of a fellow officer to a stretcher in the passageway leading topside and went to his battle station in the crews' quarters. After giving first aid to the living, he proceeded to the conn, where besides others he found the dead bodies of the captain and the executive officer. He gave first aid to an army doctor who had collapsed as a result of a broken back. He then proceeded to inspect the ship to ascertain the damage and to distinguish the living from the dead. He dragged one man topside during this tour. After making certain that everything had been checked, he gave the order to abandon ship. After the ship had been abandoned Lieutenant (jg) Szylejko boarded the rescue ship to which the more seriously injured had been removed and undertook to render medical aid to 11 unconscious men topside. He continued his efforts on board this ship and aboard a hospital ship to which he was later transferred until the pain in his chest became too terrible and he began to spit blood. The courage, professional skill and leadership displayed on this occasion were in keeping with the best traditions of the United States Naval Service." Dr. Szylejko graduated from Georgetown University School of Medicine, Washington, D. C., in 1943 and entered the service Jan. 10, 1944.

Lieutenant Charles Woodrow Styron

The Bronze Star was recently awarded to Lieut. Charles Woodrow Styron, formerly of Boston, "for heroic achievement as medical officer of an assault battalion during operations on Saipan, Marianas Islands, from June 15 to July 10, 1944. Although repeatedly in such close proximity to the enemy that mortar fire fell on his aid station and sniper fire killed persons in his vicinity, Lieutenant Styron carried on steadfastly in his ministrations to the wounded. On one occasion during heavy Japanese fire he continued to operate his station in a forward position while the remainder of the command post personnel fell back to a safer position. By his cool and capable direction of activities he was responsible for the efficient functioning of all medical personnel attached to the battalion despite the most difficult combat conditions. His gallant conduct throughout this period was in keeping with the highest traditions of the United States Naval Service." Dr. Styron graduated from Duke University School of Medicine, Durham, N. C., in 1938 and entered the service July 1, 1942.

Lieutenant Commander John Winston Fish

Lieut. Comdr. John Winston Fish, formerly of Louisville, Ky., was posthumously awarded the Bronze Star, according to the citation, "for heroic achievement while serving as flight surgeon of Air Group Eighteen, attached to the U. S. S. *Intrepid*, during air operations against enemy Japanese installations, aircraft and surface vessels in the Philippine Islands Area from Oct. 10 to Nov. 6, 1944. A skilled and courageous surgeon, Lieutenant Commander Fish continuously performed his duties under extremely hazardous conditions and made recommendations which aided materially in maintaining the Air Group's morale and physical well-being over an extended period of intensive operations. On October 29, while under intense fire from an enemy attack, he was the first to administer medical aid to the wounded and, by his quick and effective action, saved several lives that otherwise would have been lost. His heroism and unfailing good humor were an inspiration to the crew and his gallant conduct was in keeping with the highest traditions of the United States Naval Service." Dr. Fish graduated from the University of Louisville School of Medicine in 1934 and entered the service March 21, 1942.

VETERANS

WAR MANPOWER COMMISSION TO URGE ENROLMENT OF VETERANS IN MEDICAL SCHOOLS

On August 21 Mr. Paul V. McNutt, director of the War Manpower Commission, issued a release indicating that the War Manpower Commission, cooperating with the Army and Navy, will endeavor to enroll 12,000 students for the medical and dental schools of the United States this fall from among the veterans who are now available for release from the armed forces.

Of this number 8,000 are for medical schools and 4,000 for dental schools, the veterans being entitled to support for their education under the G. I. Bill of Rights. In his release Mr. McNutt stated that the Army would require permanently 10,000 physicians, the Navy 5,000 physicians and the Veterans Administration 15,000 physicians and that additional physicians would be needed for service abroad

Mr. McNutt also estimated that the overall deficiency in the United States during the postwar period would amount to 35,000 physicians.

PERMANENT ESTABLISHMENTS FOR RESTORATION OF INJURED VETERANS

Soldiers' memorials in the form of permanent establishments for the restoration of injured veterans, rather than stone and bronze monuments, is the aim of the Baruch Committee on Physical Medicine. Founded in 1944 by Bernard M. Baruch with an endowment of $1,190,000, the committee had for its purpose the development of physical medicine. The subcommittee on war and postwar physical rehabilitation and reconditioning, made up almost entirely of medical corps officers of the armed services, has sent out a blueprint of an ideal war memorial. After erection of treatment centers, and as time goes on, civilian patients, especially those injured in modern industry, may be sent to the centers by their physicians or surgeons, their care helping to meet expenses. Returned veterans may be placed in centers close to their homes. So situated they will not feel neglected and forgotten but, on the contrary, would be provided for under circumstances arranged and assembled for their rehabilitation with the sole aim of restoring them to normal life and useful activity.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

Dibble General Hospital, Menlo Park: Diagnosis and Treatment of Arthritis, Dr. Stacy R. Mettier, September 3; Nephritis, Dr. Leslie L. Bennett, September 3.

DeWitt General Hospital, Auburn:

SEPTEMBER 14 (AFTERNOON SESSION)

1 Care of Paraplegic Patients:
  a. Neurologic Lesions and Considerations, Dr. Howard Naffziger.
  b. Immediate Care of Spinal Cord Injuries, Capt. Rudolph Ziegler.
  c. Treatment of Decubitus Ulcers, Major Harry Benteen.
  d. Methods of Locomotion and Conditioning, Lieut. Jack Gregory.
  e. Program of Ambulation at DeWitt General Hospital, Lieut. Elwyn Shonyo.
  f. Urologic Care, Major D. C. Malcolm.
  g Occupational and Vocational Rehabilitation, Lieut. Col Ambrose Storck.
2. The Arthritides and Therapy, Dr. S. R. Mettier.
  a. Surgical Reconstruction, Capt Fred Rhinelander.
3. Peptic Ulcer Symposium:
  a. Diagnosis and Medical Regimen, Major J. J. Kane.
  b. Amylase Test; Diagnostic Aid in Abdominal Pain, Capt. Melvin Kirstein.
  c Roentgenologic Findings, Major Walter Scribner.
  d 4Psychosomatic Considerations, Capt Jerome Weinberger.
  e Surgical Treatment, Dr. Alton Ochsner.

SEPTEMBER 14 (EVENING SESSION)

4 Vascular Diseases.
  a Organization, Equipment and Function of a Vascular Center, Lieut. Col. Ambrose Storck
  b Classification and Medical Discussion, Capt. John Waller.
  c Anatomic Considerations and Treatment of Varicose Veins, Dr. Stanton Sherman.
  d Phlebography in Deep Venous Obstruction, Major Arthur Koepsell.
  e. New Method for Testing and Developing Collateral Circulation, Captain Massell.
  f. Treatment of Arteriovenous Aneurysm, Major Norman Freeman.
  g Basic Vascular Tone in Sympathectomy, Lieut William Rector.

SEPTEMBER 15 (AFTERNOON SESSION)

5 Surgical Treatment of Empyema, Dr. Alton Ochsner.
6 The Alcoholic Patient, Dr. Alexander Simon.
7. Outline of Care of Psychiatric Patients, Major Daniel Sullivan.
8 Pulmonary Coccidioidomycosis, Dr Charles Smith.
9. Inguinal Hernia
  a Anatomic Considerations, Dr John Saunders
  b Repair of Primary and Recurrent Hernia, Major Harry Benteen.
10 Orthopedic Presentations:
  a. Reconstructive Surgery of the Hand, Dr. Sterling Bunnell.
  b Experience in Treatment of Compound Fractures, Lieut. Col. E. K. Prigge.
  c. Treatment of Severely Injured Elbow, Capt. Elbert Davis.

SEPTEMBER 15 (EVENING SESSION)

11 Neurosurgical Symposium:
  a. Diagnosis of Protruded Intervertebral Disk, Capt. Manuel Sall.
  b. Surgical Treatment and Prognosis of Protruded Intervertebral Disk, Lieut Comdr. Keith Bradford.
  c. Correction of Cranial Defects, Major Tracy Haverfield.
  d. Peripheral Nerve Repair, Lieut. Bertram Selverstone.
  e. Management of Combined Bone and Nerve Lesions, Capt. Jerome Sweeney.
  f. Reeducation of Aphasic Patients, Lieut. Joseph Wepman.
12 Methods of Therapy in Dermatoses, Capt. Eugene Bereston.
  a Roentgen Therapy and Cautions, Major Walter Scribner.
13. Penicillin Therapy in Chronic Sinusitis, Capt. Robert Chait.
14. Administration of Fluids, Plasma and Blood in Prolonged Surgery, Major G. C. Langsdorf.
  a. Laboratory Adjuncts in Blood Matching and Blood Bank, Lieut. Col Irving Madoff.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, July 28, page 959)

CALIFORNIA

St Joseph's Hospital, San Francisco. Capacity, 245; admissions, 7,327 Sister M. Raymond, Superior (interns, January 1 and April 1, 1946)

Santa Clara County Hospital, San Jose. Capacity, 453; admissions, 4,682 Dr Henry E Dahleen, Superintendent (resident—tuberculosis, disqualified for military service).

CONNECTICUT

Bridgeport Hospital, Bridgeport Capacity, 416; admissions, 10,234. Mr Oliver H. Bartine, Superintendent (interns, April 1, 1946).

ILLINOIS

Belmont Community Hospital, Chicago. Capacity, 125; admissions, 4,180. Mrs. Gertrude F Scofield, Superintendent (interns, September 1945; January and July 1946)

MASSACHUSETTS

Memorial Hospital, Worcester Capacity, 215; admissions, 7,713. Dr. Winthrop B. Osgood, Superintendent (3 interns).

NEW YORK

Auburn City Hospital, Auburn. Capacity, 355; admissions, 6,198 Mr. Jerome F. Peck Jr., Acting Superintendent (resident—mixed service).

Coney Island Hospital, Brooklyn. Capacity, 300, admissions, 5,519. Dr. Saul M. Penner, Superintendent (6 interns)

Israel Zion Hospital, Brooklyn. Capacity, 518; admissions, 9,867. Dr J. Prager, Executive Director (interns, October 1, 1945; April 1, 1946)

PENNSYLVANIA

Western State Psychiatric Institute and Clinic, Pittsburgh Capacity, 136; admissions, 104. Dr. Grosvenor B. Pearson, Director (12 residents—psychiatry, including 10 disqualified for military service)

UTAH

St Mark's Hospital, Salt Lake City Capacity, 238; admissions, 4,838. Mrs Olive V. Wardrop, Superintendent (intern, October 1).

Thomas D Dee Memorial Hospital, Ogden. Capacity, 400; admissions, 8,405 Mr L. H Evans, Superintendent (interns)

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Personal.—Dr. Jacob C. Geiger, director of public health of the city and county of San Francisco, was recently awarded the decoration of the Orden de Vasco-Nunez de Balboa, grade of Knight Commander, for services to Panama.

Alameda County Society Begins Monthly Bulletin.—With the August issue the *Bulletin of the Alameda County Medical Association* made its appearance. The cover shows the Oakland bridge, and the contents discuss the proposed activities of the association under a recently inaugurated "accelerated program." Dr. Milton H. Shutes is the editor.

FLORIDA

Election of State Medical Board.—Dr. Joseph B. Kollar, Vero Beach, was elected president of the Florida State Board of Medical Examiners at a meeting in Jacksonville June 25, succeeding Dr. Howard G. Holland, Leesburg. Dr. Frank D. Gray, Orlando, was named vice president and Dr. Harold D. Van Schaick, Miami, was reelected secretary-treasurer.

GEORGIA

Personal.—Mrs. Stewart R. Roberts has been appointed assistant secretary of the Fulton County Medical Society, effective July 1.

Edwin Watson Resigns.—Dr. Edwin R. Watson has resigned as director of the division of maternal and child health of the Georgia State Department of Public Health to enter private practice in Macon. He has been connected with the state department for eight years. Dr. Guy G. Lunsford, director of local health organizations, will serve as acting director of the maternal and child health division, according to *Georgia's Health*.

Rabies Control Supervisor Named.—Leland Edson Starr, Ph.D., formerly assistant dean of the school of veterinary medicine and professor of pathology, Alabama Polytechnic Institute, and recently in private practice of veterinary medicine in Roanoke, Va., has been appointed state rabies control supervisor with the Georgia Department of Public Health, effective July 12. Dr. Starr will assist counties in setting up local organizations for rabies control, in accordance with the new rabies control law which requires vaccination of all dogs, according to *Georgia's Health*.

ILLINOIS

Personal.—Dr. Sandor Horwitz, Peoria, recently completed fifty years in the practice of medicine.——Dr. and Mrs. Edward A. Elfeld, Arlington Heights, recently celebrated their fiftieth wedding anniversary.

Sixteen Deaths from Poliomyelitis.—An outbreak of infantile paralysis in Rockford and surrounding area has been responsible for 140 cases and sixteen deaths since July 1, newspapers report. Rockford reported 71 cases, Winnebago County 61 and Stephenson, Boone and Carroll counties 8.

Chicago

Appointments in Pharmacology at Illinois.—Dr. Carl C. Pfeiffer has been appointed professor and head of the department of pharmacology, materia medica and therapeutics at the University of Illinois College of Medicine, effective on his release from the U. S. Navy, August 15. Dr. Pfeiffer graduated at the University of Chicago School of Medicine in 1937. He was pharmacologist with Parke, Davis & Co. from 1941 to 1943, when he entered the Navy. Earl Randall Loew, Ph.D., research pharmacologist with Parke, Davis & Co., has been named associate professor of pharmacology, materia medica and therapeutics, and Dr. Klaus R. W. Unna, formerly research associate with the Merck Institute of Therapeutic Research, Rahway, N. J., and recently instructor in pharmacology, University of Pennsylvania School of Medicine, Philadelphia, has been named assistant professor in the department of pharmacology at Illinois.

INDIANA

George Clowes Retires.—George Henry Alexander Clowes, Ph.D., since 1920 director of the research laboratories of Eli Lilly and Company, Indianapolis, has retired.

State Meeting Canceled.—The 1945 annual session of the Indiana State Medical Association, which was scheduled for French Lick Springs, October 2-4, has been canceled. The regular annual meeting of the house of delegates will be held sometime in the future at Indianapolis on the call of the president.

Physician Receives Service Award.—Dr. Harold P. Graessle, Seymour, was recently presented with the first annual "Seymour Distinguished Service Award" to be sponsored annually by the Seymour Rotary Club. The recipient of the award can be any citizen of the Seymour area who has rendered a service during the previous eighteen months that will have a lasting influence on the life in Seymour, it was stated.

MAINE

Reappointments to Medical Board.—Governor Horace A. Hildreth on July 11 reappointed Dr. Adam P. Leighton, Portland, and Dr. Currier C. Weymouth, Farmington, as members of the Maine Board of Registration of Medicine. Dr. Leighton, with his reappointment, began his thirty-first year as member and secretary of the board.

MARYLAND

Communicable Disease Control Ordinance Enacted.—An ordinance has been enacted by the city council of Baltimore to strengthen the program of the city health department to prevent communicable diseases in Baltimore. The ordinance authorized the commissioner of health to make and adopt rules and regulations to prevent and control the spread of communicable diseases and to provide punishment for any violations.

Southern Health District.—The city council has recently enacted an ordinance providing for the acquisition of land and construction thereon of a health center in south Baltimore to be known as the Southern Health District Building. While the Eastern Health District was established in 1932, the Western Health District in 1935, the Southeastern Health District in 1937 and the Druid Health Center in 1939, the new Southern Health District edifice will be the first building excepting Sydenham Hospital ever to be erected in Baltimore expressly for the use of the city health department. The commissioners of finance of the city are empowered to issue certificates of indebtedness to an amount not exceeding two million dollars to finance the project.

Rodent Control Study.—John T. Emlen Jr., Ph.D., Davis, Calif., has been appointed research associate in the department of parasitology of the Johns Hopkins School of Hygiene and Public Health to take charge of investigations on rodent ecology and control, according to *Science*. The program, supported by a grant from the Rockefeller Foundation, is being carried out with the cooperation of the rodent control division of the city of Baltimore. It is a continuation and expansion of the field studies which Curt P. Richter, Ph.D., of the Johns Hopkins University School of Medicine developed during the last three years in cooperation with this division. Dr. Richter will serve on the advisory committee for this expanded program and is continuing his laboratory investigations on the behavior of wild rats as part of the new program.

MICHIGAN

State Meeting Canceled.—The proposed 1945 annual session of the Michigan State Medical Society has been canceled.

Changes in Health Officers.—Dr. Joseph A. Murphy was recently appointed health officer of Whitehall. Dr. Albert E. Heustis Jr. has been named director of Branch County with headquarters in Coldwater, succeeding Dr. Ira O. Church, who resigned to go to California (THE JOURNAL, July 7, p. 742). Dr. John J. Angel has been appointed village health officer of Wayne.

Personal.—Dr. Thomas E. DeGurse, Marine City, was recently guest of honor at a dinner in recognition of his completion of fifty years in the practice of medicine. He was presented with a leather portfolio, and speakers at the dinner included Drs. Andrew S. Brunk, Detroit, L. Fernald Foster, Bay City, president and secretary respectively of the Michigan State Medical Society, Oscar D. Stryker, Fremont, Clarence E. Umphrey and Eldwin R. Witwer, Detroit, councilors of the state society, and William J. Burns, LL.B., Lansing, executive secretary of the society. Dr. DeGurse has served

as councilor of the state medical society and president of the St. Clair County Medical Society. — Arthur D. Emmett, Ph.D., assistant director of research with Parke, Davis & Company, Detroit, retired July 1 to become consultant. Dr. Emmett has been in charge of the vitamin division for twenty-nine years.

Clinical Teaching in Internal Medicine.—The department of postgraduate medicine of the University of Michigan Medical School, Ann Arbor, has arranged a clinical teaching program for every Thursday afternoon beginning September 13 and continuing through December 20 at the University Hospital. The program is designed to serve the needs of practicing physicians who are interested in problems of internal medicine. It will consist of clinical discussion on ward rounds conducted each day by two different members of the senior staff of the department of internal medicine and will end with a conference of the entire medical staff and review of recent interesting electrocardiograms.

MINNESOTA

Illegal Practitioner.—On July 6 Mrs. Florence M. Johnson, Minneapolis, was sentenced by Judge Frank E. Reed of the district court to a term of one year in the Hennepin County Jail following her plea of guilty to a charge of practicing massage without a license. The sentence was stayed for one year on condition that the defendant close her office, dispose of her equipment and absolutely refrain from the practice of healing or massage in any manner in the future. In investigation the state board of medical examiners showed that Mrs. Johnson had opened an office in the Medical Block, Minneapolis, in April 1945 and that she had in her possession a certificate dated June 24, 1940, which she had obtained from the Minnesota Clinical Institute, Minneapolis. The certificate was signed by John LeMay, president, and Dr. Cornelius W. Wall. The physician died in January 1944 and LeMay was under arrest on July 13 charged with practicing healing without a basic science certificate. Mrs. Johnson was operating a massage and bath parlor under the name of Fredjohn Health Center, charging $3 for her treatments.

MISSISSIPPI

Personal.—Dr. Rosier D. Dedwylder, Cleveland, on July 1 completed twenty-five years' service as director of the Bolivar County Health Department.

Medical Society Votes Against Four Year Medical School.—The Lauderdale County Medical Society, in special session July 12, adopted resolutions to the effect that the establishment of a four year medical school is not the answer to supplying an adequate number of doctors for rural citizens of Mississippi, according to the Jackson *News*. It was stated further that "the time is not propitious for establishing a four year school of medicine in Mississippi."

MISSOURI

Special Society Election.—Dr. Richard G. Helman, Kansas City, was recently elected president of the Kansas City Obstetrical and Gynecological Society. Other officers include Drs. Russell D. Etzenhouser, Independence, vice president, and John O. Kennedy, Kansas City, secretary-treasurer.

Health Lectures.—The Jackson County Health Forum will open its 1945-1946 lecture series on September 19 with a talk by Dr. Robert M. Stecher, Cleveland, on "Arthritis and Gout." "Medical Care for the American People" will be the theme of a symposium on October 17 with Senator Claude Pepper, Washington, D. C., and Dr. Louis H. Bauer, Hempstead, N. Y., Trustee of the American Medical Association, as speakers and with Dr. Morris Fishbein, Editor of THE JOURNAL, as moderator and interlocutor. Other lecturers in the series will be:

Dr. Irvine H. Page, Cleveland, November 21, High Blood Pressure and Your Kidneys.
Dr. Henry H. Turner, Oklahoma City, January 16, Your Glands Your Dynamo.
Dr. Walter H. Theobald, Chicago, February 20, Sinus and Colds.
Dr. Derrick T. Vail, Cincinnati, March 20, Save Your Eyesight.
Dr. Fishbein, April 17, Diet and Health.

OHIO

Legislation Concerning Health.—Recently enacted legislation, effective September 28, limits the use of the Ohio State Sanatorium, Mount Vernon, to the care and treatment of the mentally ill, mentally deficient and epileptic patients suffering from tuberculosis. Another bill appropriates $1,190,000 to the welfare department for construction and equipment at the sanatorium. A bill, effective September 21, makes definite that a child of school age afflicted with tuberculosis is included in the state educational program and sets at rest the question of responsibility for the education of the child.

New Department of Clinical Biochemistry.—Victor C. Myers, Ph.D., professor and head of the department of biochemistry, Western Reserve University School of Medicine, Cleveland, has been named director of a newly created department of clinical biochemistry at the school. The present department of biochemistry will be enlarged and a new director selected.

Appointment in Hearing and Speech Therapy.—Warren H. Gardner, Ph.D., San Mateo, Calif., has been appointed professor of hearing and speech therapy at Western Reserve University School of Medicine and director of clinical services of the Cleveland Hearing and Speech Center, according to the Cleveland *Press* of July 6. The appointment will be effective September 1. Dr. Gardner has been associated with the California state department of public health and has been conducting tests on school children of the state. The Cleveland Hearing and Speech Center recently was formed by the Cleveland Hearing Center and Speech Clinic at Western Reserve University (THE JOURNAL, June 9, p. 453).

Industrial Accidents.—The Ohio Industrial Commission recently reported that, of the 328,121 claims filed during 1943, 1,104 were for fatalities, 8 for permanent total disability, 2,797 for permanent partial disability, 46,604 for temporary disability over seven days, 25,860 for temporary disability of seven days or less and 251,748 for temporary disability which resulted in no time loss. The days lost through disabilities totaled 10,106,407. In 1943 the six principal agencies causing industrial accidents in the order of their standing were machinery 72,601 claims with 44 fatalities, hand tools 34,283 with 13 fatalities, metal stock (not otherwise listed) 34,487 with 11 fatalities, bundles, barrels, boxes, benches and the like 21,707 with 18 fatalities, flying objects, dust, cinders and the like 16,433 with no fatalities and pipes, rods, sheets or plates 17,173 with 12 fatalities.

PENNSYLVANIA

$100,000 for Cancer Research.—The Pennsylvania State Department of Health will receive $100,000 or what part of the sum may be needed to conduct cancer research to determine the cause, mortality rate, methods of treatment, prevention and cure of cancer and allied diseases, including the nature and extent of the facilities available in the counties and cities of the state for the diagnosis and treatment of these diseases. The appropriation was provided for in a bill recently signed by Gov. Edward Martin, according to the *Field Army News*.

Philadelphia

Lester Burket Named Professor of Oral Medicine.—Dr. Lester W. Burket, assistant professor, has been appointed professor and head of the department of oral medicine at the University of Pennsylvania Dental School.

George W. Raiziss Dies.—George W. Raiziss, Ph.D., head of the department of chemistry of the Dermatological Research Laboratories and later director of that organization on its merger with Abbott Laboratories, died July 16 in the Atlantic City Hospital, Atlantic City, N. J.

Pittsburgh

Course in Clinical Allergy.—The University of Pittsburgh School of Medicine announces an orientation course in clinical allergy, October 1-5, under the auspices of the American Academy of Allergy. The course will include lectures, demonstrations, case presentations and laboratory procedures covering all aspects of allergy. Round table discussions will be held in the evening. Allergists and internists from various parts of the country will make up the teaching faculty. Additional information may be obtained from Dr. William S. McEllroy, dean of the University of Pittsburgh School of Medicine.

SOUTH CAROLINA

Physician Wins Service Award.—Dr. Warren H. Burgess has been awarded the A. T. Heath Award for public service to the people of Sumter. The award, given annually by representatives of the city's four service clubs, consists of a silver service. Dr. Burgess has been practicing in Sumter since 1911 and has been city physician since 1914. He graduated at the Medical College of South Carolina, Charleston, in 1910.

Medical College Appointments.—Dr. John A. Boone, assistant professor of medicine, has been appointed assistant dean at the Medical College of the State of South Carolina, Charleston. Other changes noted in the Charleston *Evening Post*, June 16, included the election of Dr. Charles Frederick Williams as professor emeritus of psychiatry and the appointment of Dr. Coyt Ham as clinical professor of psychiatry. A reorganization of the neuropsychiatric department of the medical college also was announced. Dr. Douglas B. Remsen, assistant professor of medicine, is reported to have indicated that he would give up his private practice and serve as acting head of the reorganized department.

TENNESSEE

Ninety-Two Years of Age.—Dr. Henry C. Martin, Cookeville, on July 10 observed his ninety-second birthday. Dr. Martin graduated at Vanderbilt University School of Medicine, Nashville, in 1894.

Examining Board Election.—Dr. James H. Keeling, Knoxville, was elected president of the Tennessee State Board of Medical Examiners at its annual meeting in Nashville July 10, succeeding the late Dr. James K. P. Blackburn, Pulaski. Other officers include Drs. Thomas B. Yancey, Kingsport, vice president, and Harley W. Qualls, Memphis, secretary.

Personal.—Dr. William W. Frye, professor and head of the department of preventive medicine and public health, Vanderbilt University School of Medicine, Nashville, has been granted a six months leave of absence to serve on a special commission sent to China by the UNRRA to study the current cholera epidemic there, it is reported. During Dr. Frye's absence Dr. Alvin E. Keller will be acting head of the department of preventive medicine and public health.——Dr. Louis Levy, Memphis, was reelected president of the Memphis Symphony Society, Inc., June 19.

Changes in University Faculty.—Dr. Frank E. Whitacre has been promoted from associate professor to professor of obstetrics and gynecology and head of the division at the University of Tennessee College of Medicine, Memphis. Dr. William T. Pride, who is relieved as head of the division, will continue as professor. Dr. Whitacre, who from 1939 to 1941 was professor of obstetrics and gynecology and head of the department, Peiping Union Medical College, Peiping, China, was for two years interned in Manila by the Japanese. He has been connected with the university since January. Dr. James R. Reinberger has been promoted to professor of obstetrics and gynecology. Hugo M. Krueger, Ph.D., St. Louis, associate professor of pharmacology, St. Louis University School of Medicine, has been appointed assistant professor of pharmacology. Dr. Isadore N. Dubin, instructor and associate in pathology, Duke University School of Medicine, Durham, N. C., has been appointed assistant professor of pathology and bacteriology.

UTAH

Activities at Utah Medical School.—The Utah Medical Foundation has been established and incorporated at the University of Utah School of Medicine with a gift of $2,850 by the first graduating class of the four year school. The objective is to promote the cooperation of alumni and friends of the medical school in improving the undergraduate, graduate and research functions and to establish scholarships, lectureships, professorships, research and student loan funds. One of the first activities of the foundation was the establishment of the "Dr. W. R. Tyndale Lectureship in Medicine," honoring Dr. William R. Tyndale, a member of the staff of the Utah school since 1912. Dr. George W. Thorn, Hersey professor of the theory and practice of physic, Harvard Medical School, Boston, was the first speaker under the lectureship recently, discussing "The Role of Endocrine Glands in Adaptation" and "Fatigue of Thyroid and Adrenal." The U. S. Public Health Service has given a grant of $92,000 to the medical school for research in muscular dystrophy and related degenerative disorders. Dr. Maxwell M. Wintrobe, professor of medicine, is director of the study, to which an advisory committee of nationally known scientists will be appointed. The Church of Jesus Christ of Latter-Day-Saints has given the medical school $25,000 for rehabilitation, modernization and purchase of supplies and equipment for the department of pharmacology and physiology. New appointments include those of Horace W. Davenport, Ph.D., formerly associate in physiology, Harvard Medical School, Boston, as professor and head of the department of physiology, and George Sayers, Ph.D., formerly research assistant in physiologic chemistry (instructor) at Yale University, New Haven, as assistant professor of pharmacology.

VIRGINIA

Portrait of Harvey Jordan.—A feature of the recent commencement of the University of Virginia Department of Medicine, Charlottesville, was the presentation by members of the graduating class of a portrait of Dr. Harvey E. Jordan, dean. The presentation was made by Dr. Frederick V. Vance Jr., Bristol, Tenn., medical class president, and the speech of acceptance was given by John Lloyd Newcomb, LL.D., president of the university.

WEST VIRGINIA

Personal.—Dr. Hu C. Myers, Philippi, and Mr. John Hart, Charleston, have been appointed by Governor Clarence W. Meadows as members of the advisory committee to the legislative interim committee created for the purpose of making a complete study of public health problems in West Virginia (THE JOURNAL, June 23, p. 606). Dr. Myers is a past president of the Hospital Association of West Virginia and represents that organization on the advisory committee. Mr. Hart, who is director of Hospital Service, Inc., and Medical Service, Inc., Charleston, represents the medical-hospital service plans operating in West Virginia. The committee now has ten members.

WISCONSIN

Director Named for Hospital Survey.—Vincent F. Otis, business administrator of the Milwaukee County Asylum for Chronic Insane, Wauwatosa, has been appointed director of the hospital and health center survey in Wisconsin which was recently authorized by the state board of health. Mr. Otis will be responsible for the organization and supervision of the collection and analysis of facts pertaining to a statewide survey and the evaluation of plans and specifications for new and improved hospital buildings and health center needs. The recently organized state hospital advisory committee has agreed that "Hospital Schedules of Information" of the Commission on Hospital Care would be used for obtaining the desired information, and the commission's Public Health Center Schedules of Information would be used to gather the information concerning available health center facilities. Dr. Gunnar Gundersen, La Crosse, president of the state board of health, is the chairman of the state hospital advisory committee. Members of the committee's executive committee include Dr. Harold M. Coon, superintendent of the State of Wisconsin General Hospital, Madison; Mr. Charles H. Crownhart, Madison, secretary of the state medical society, and Dr. Carl N. Neupert, Madison, secretary of the state board of health.

GENERAL

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended August 11 have been received from the division of public health methods, U. S. Public Health Service, as follows:

Division and State	Poliomyelitis Week Ended 8/11, 1945	Poliomyelitis Week Ended 8/12, 1944

LATIN AMERICA

Health Activities in Latin America.—*Nonmilitary Personnel to Receive Army Aid.*—The services and facilities of the Army medical department will be available to "non-Army personnel, their dependents and servants living at military stations in the Panama Canal Department" under a program announced in July. Dependents are classified as "wives, children, dependent husbands or other members of a family residing with War Department employees." Treatment will be furnished by army medical officers. According to an announcement, a medical officer will be permitted to call on patients in their quarters only when they are unable to walk to the dispensary. Civilian employees whose places of duty are at locations other than at the post at which they reside, who require medical attention during duty hours, may visit the station dispensary where employed. Patients requiring hospitalization will be sent to the Gorgas, Ancon, C. Z., and Margarita, C. Z., hospitals on the Pacific and Atlantic sides respectively.

Health Center Established.—A health center has been established in Iquitos, Peru, by the Servicio Cooperative Interamericano de Salud Publica. The building was made available by the former Peruvian agency known as the Supervision de Sanidad de la Montana. Beginning January 1947 the ministry of health and social welfare of Peru will be responsible for the maintenance of the health center. The health center is in connection with the policlinic that has been functioning for more than a year. Dr. Jorge Atkins is director.

FOREIGN

Tribulations of the Netherlands Red Cross.—Officials of the Netherlands Red Cross have had to wage a continuous struggle during the five years of the occupation to prevent the organization from falling under the complete domination of the Nazis. In their attempts to make the party-controlled "Winter Help" fund the sole relief agency in the country the occupation authorities placed all kinds of handicaps in the way of the Red Cross officials, according to the Netherlands Information Bureau. When it became known that the Germans would name the Dutch Nazi head of "Winter Help" secretary-general of the Red Cross, the entire staff worked night and day to remove their stocks to safe places, so that the Germans were unable to hand them over to the wehrmacht. At the same time 98 per cent of the staff resigned and the group was forced to operate clandestinely. In reprisal the Germans arrested several staff members and kept them in jail for various periods. They also confiscated all ambulances and automobiles on the pretext that they had been used to transport ammunition for the underground movement. But despite all German efforts, the staff members of the Red Cross continued their work in secret. Transport drivers who had gone into hiding to evade the German Security Police distinguished themselves on March 3 when The Hague was erroneously bombed by the Royal Air Force. The chairman of The Hague branch, Dr. Pieter Jelle Dietz, and several nurses were killed while on their way to help victims of that attack.

UNRRA Activities.—According to a recent report Lieut. Col. Virgil P. Sydenstricker, chief of the nutrition section, United Nations Relief and Rehabilitation, and Dr. Arnold P. Meiklejohn, specialist in nutrition attached to the Rockefeller Institute for Medical Research on leave to the UNRRA, were assisting in rehabilitation work in the concentration camp of Belsen.——Col. Daniel F. Wright, U. S. Public Health Service, now chief consulting engineer of the UNRRA sanitary department, Greece, is planning a project to eradicate malaria from Greece, where, it is reported, 87 per cent of the country is infected with the disease. The country will be divided into ten districts, to each of which will be assigned one physician, two sanitary engineers, nurses and the team of fifteen sanitary inspectors. It is planned to clear swamp lands through the use of DDT and to effect a cure of infected persons through the use of quinine.——Dr. Dudley A. Reekie, Minneapolis, on leave from the United States Public Health Service to work with the United Nations Relief and Rehabilitation Administration and now commanding medical officer of the UNRRA mission in Italy, reports that tuberculosis and malaria are being brought under control by projects carried forward in cooperation with the Italian government. The effect of the war has been to increase sharply the incidence of both diseases. The flooding and mining of the Anopheles breeding Pontine marshes by the Nazis during the occupation brought about renewed outbreaks of malaria; tuberculosis is being spread by returning Italian nationals who became infected in Germany. A preliminary survey to discover the incidence of malaria in the Pontine area carried out this spring at Fondi in the province of Latinia showed that 100 per cent of the population living in that section were infected. Flooding and mining of the area is slowing down the work of malaria prevention. However, for the control of the adult malaria-carrying mosquito UNRRA has shipped 45,000 square feet of window screening, which is being distributed to the people. Enough DDT oil solution to spray 1,200 houses in the most heavily mined or flooded districts has been made available. UNRRA will also provide trucks, bicycles and funds for the necessary labor of cleaning ditches and spraying chemicals. The UNRRA malaria control project is under the direction of Lieut. Col. Vincent B. Lamourex, an epidemic control engineer, who is chief consultant with the UNRRA staff in Italy. Plans are now in progress to send units of Italian engineers into other parts of the country to supervise malaria control work throughout the malaria season. This work is supplementary to the malaria programs of the military command and the Italian government.

Government Services

Regular Corps Appointments for Medical Officers in the U. S. Public Health Service

A competitive examination for appointment in the Regular Corps in grades of Assistant Surgeon (1st Lieutenant) and Senior Assistant Surgeon (Captain) will be held on the dates listed in the table.

Regular Corps appointments are permanent in nature and provide unique opportunities to qualified doctors for a life career in one or more of a large number of fields including research, general hospitals, special hospitals, foreign duty and federal, state and local public health programs. Assignments are made with all possible consideration of the officer's demonstrated abilities and experience. There is ample opportunity for professional growth and development. Examinations will be oral and written. The oral examination will be held at 9 a. m. at the several places listed on the dates shown. The written examination will be held on October 8, 9 and 10 at places convenient to the candidate and the service. Applicants for the grade of Assistant Surgeon must be citizens of the United States, must present diploma of graduation from a recognized medical school, must have had or be in process of completing an internship or its equivalent and must have a physical examination at place of oral examination by medical officers of the service. Applicants for the grade of Senior Assistant Surgeon must meet the aforementioned requirements and must have had an additional four years of training or experience. Application forms may be obtained by writing to the Surgeon General, U. S. Public Health Service, Bethesda Station, Washington 14, D. C.

Entrance pay for Assistant Surgeon with dependents is $3,411 a year and for Senior Assistant Surgeon with dependents is $3,991 a year. Promotions are at regular intervals up to and including the grade of Medical Director, which corresponds to full Colonel at $7,951 a year. Retirement pay at 64 is $4,500 a year. Full medical care, including disability retirement at three-fourth's pay, is provided. All expenses of official travel are paid by the government. Thirty days' annual leave with pay is provided. All commissioned officers have full military status for the duration of the present war.

Places and dates of oral examinations:

Atlanta, Ga.—Malaria Control in War Areas, 605 Volunteer Building	Sept. 13
Baltimore—Marine Hospital, Wyman Park Drive and 31st Street	Oct. 1
Boston—Marine Hospital, 77 Warren Street (Brighton)	Sept. 10
Chicago—Marine Hospital, 4141 Clarendon Avenue	Sept. 25
Cleveland—Marine Hospital, Fairhill Road and E. 124th Street	Sept. 27
Detroit—Marine Hospital, Windmill Pointe	Sept. 26
Fort Worth, Texas—U. S. Public Health Service Hospital	Sept. 15
Kansas City, Mo.—U. S. P. H. S. District No. 7, 603 B. N. A. Building	Sept. 22
Kirkwood, Mo., near St. Louis—Marine Hospital, 525 Couch Avenue	Sept. 24
Los Angeles—U. S. P. H. S. Relief Station, 406 Federal Building	Sept. 17
New Orleans—Marine Hospital, 210 State Street	Sept. 14
New York—Stapleton, Staten Island, Marine Hospital	Sept. 11
Norfolk, Va.—Marine Hospital, Hampton Boulevard Larchmont	Sept. 12
San Francisco—Marine Hospital, 14th Avenue and Park Boulevard	Sept. 18
Seattle—Marine Hospital, Judkins Street and 14th Avenue, South	Sept. 20
Washington, D. C.—U. S. P. H. S. Dispensary, Fourth and D Streets S.W.	Oct. 2

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 31, 1945.

The Farewell of the American Medical Officers

The forces of the United States are leaving this country with, of course, their medical officers. From the European Theater of Operations Major Gen. P. R. Hawley has written to the British Medical Association expressing great regret at their departure, which breaks the happy links formed with the medical profession in Britain. He states that it is his pleasant privilege as well as his urgent duty to express to the British Medical Association the deep appreciation of the medical officers "for all the courtesies extended to them by your splendid organization." The *British Medical Journal* says that the departure of the Americans will be sincerely regretted by their British colleagues. The presence of the American medical officers has been like a refreshing breeze at the British Medical Association House, the Royal Society of Medicine and elsewhere. In clinical and scientific meetings they have thrown their experience and ideas freely into the common pool. Many permanent friendships have been made, and the cause of Anglo-American unity has been greatly advanced by this most welcome of war invasions.

New Clinic for the Investigation of Deafness and Hearing Aids

The Medical Research Council has for some years been concerned with the problems of deafness through its committee on the physiology of hearing. It has recently formed three research committees—one to deal with the medical and surgical problems of deafness, the second to consider the design and performance of electroacoustic equipment, and the third to look into the education of the deaf. The provision of a suitable deaf aid at a reasonable cost and with easy maintenance is an urgent need for those who can be so relieved. The council is opening at the National Hospital, London (the great center of British neurology), a special clinic for the investigation and treatment of all kinds of deafness except that accompanied by active otitis with ear discharge. The Otological Research Unit will be under the direction of Dr. C. S. Hallpike, aural physician to the National Hospital and a member of the scientific staff of the Medical Research Council and of its Electroacoustics Committee. The new clinic should prove most useful, for the large number of persons who now require hearing aids can obtain them only at exorbitant prices, and their maintenance is an additional burden.

Grant from Great Chemical Firm for Scientific Research in India

As previously reported in THE JOURNAL (July 29, 1944, p. 924) the physiologist Prof. A. V. Hill, F.R.S., returned from a mission to India on behalf of the Royal Society. In his report to the society he stressed the need for greater scientific cooperation of British and Indian science. In spite of brilliant achievements Indian science is too narrowly based for the demands to which it will be subjected by the immense program of national reconstruction now being worked out. Britain can lend valuable aid by facilities for Indian research workers in this country, by lending scientists to India and by establishing effective liaison between the two countries. The main work will fall on the specialists societies in India, whose work is likely to be coordinated in the future by a minister of the government. Among the Indian societies Professor Hill particularly commended the National Institute of Sciences of India as best suited to form a scientific academy comparable to the Royal Society of London. A munificent offer has been made to it.

Lord McGowan, president of Imperial Chemical Industries, has written to Professor Wadia, president of the National Institute of Science of India, offering a number of research fellowships for the encouragement of Indians in chemistry, physics and biology, to be held at Indian universities and institutions. The sum offered is $100,000 over the next five to seven years. In his letter Lord McGowan states that until recent years the Royal Society was hampered by lack of funds and provision for the maintenance of scientific workers. This difficulty was overcome by the generosity of various benefactors including industrialists such as Mond and Messel. There seemed no better way of encouraging the advance of science in India and with it the general prosperity of the country than by offering these fellowships. Each will be worth $110 a month and will be tenable in the first instance for two years with possibility of extension up to three years. In addition there will be a grant for research expenses. The fellowships will be open to persons irrespective of sex, race or religion who are under the age of 35 years.

Great Hospital of the British Army Handed Back by the Americans

Eighteen months ago the British army handed over to the United States Army in this country its historic and greatest hospital, the Royal Victoria Hospital, Netley. The ceremony was described in THE JOURNAL at the time, but for security reasons the location was not given. In another picturesque ceremony the hospital has been returned to the British army by Brig. Gen. Charles B. Spruit, United Kingdom base surgeon of the United States Army. In receiving back the hospital Sir Alexander Hood, Director General of the Army Medical Service, said "We of the British Army Medical Service would like our American friends to have a tangible token to remind them of their stay here. I therefore present to the United States Medical Services the key of the hospital. I hope it will remind them not only of Netley but also of the fact that our services, which have so long been mutually supporting one another, are for all time united." Though the main buildings of Netley have been handed back, the American Medical Services still retain a hospital within its grounds.

Rockefeller Traveling Fellowships to Be Resumed

It is announced by the Medical Research Council that preliminary arrangements have been made for the resumption of the Rockefeller Medical Fellowships. These are provided from a fund entrusted to the council by the Rockefeller Foundation of New York. The fellowships are intended for graduates resident in Britain who have had some training in research work in clinical medicine or surgery or some other branch of medical science and who are likely to profit by a period of work at a center in the United States or elsewhere abroad before taking up positions for higher teaching or research in Britain. It is hoped to make a limited number of awards during the academic year 1945-1946, depending on the availability of candidates and the facilities for travel.

Munificent Grant by Wellcome Trustees for Rebuilding of Royal College of Surgeons

The late Sir Henry Wellcome of the firm known all over the world as Burroughs Wellcome & Co. was a great philanthropist who devoted his wealth to the endowment of research. He settled in England and in 1923 resolved to consolidate his many interests in this country, America and elsewhere—research laboratories, medical museums and libraries, development and manufacturing laboratories, distributing companies and organizations. For this purpose he formed the Wellcome Foundation. He died in 1936 at the age of 82 and left a will unique among

testamentary documents. All the shares in the foundation were vested in five trustees, whose aim he laid down to be "the advancing of research work bearing upon medicine, surgery, chemistry, physiology, bacteriology, therapeutics, materia medica, pharmacy and allied subjects." During his life he founded in London the Wellcome Laboratories of Tropical Medicine, the Wellcome Historical Medical Museum and Library and the Wellcome Museum of Medical Science, as well as other laboratories. He empowered his trustees to make grants for the foundation and extension of museums. They have granted $400,000 for the construction of three new museum floors at the Royal College of Surgeons on condition, according to the terms of the trust, that the name "Wellcome" is associated with the extension. The council of the college gratefully received the offer and decided to name one of the new buildings the "Sir Henry Wellcome Wing." The damage done to the college by German bombs has been described in previous letters to THE JOURNAL.

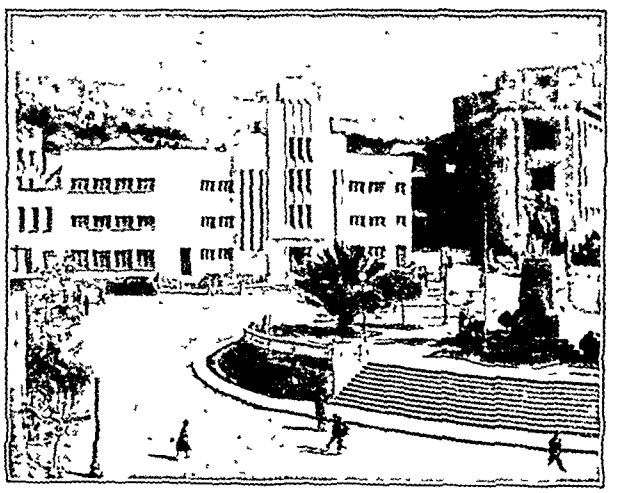
Legal Decision that an Antivivisection Society Is Not a Charity

The National Anti-Vivisection Society claimed exemption from income tax on the ground that it was a body established for charitable purposes only. Mr Justice Macnaghten has decided to the contrary, as the main object of the society was the total abolition of vivisection, and it had been proved that, if experiments on living animals was discontinued, it would constitute a serious obstacle to obtaining further medical knowledge of benefit to the public.

BOLIVIA

(From Our Regular Correspondent)

LA PAZ, July 31, 1945.



American Health Mission to Bolivia

The United States, through the Institute of Inter-American Affairs and its three divisions of Health and Sanitation, Food Supply and Training, offered to all Latin American republics its aid in furthering their health. In June 1942 Dr. Eugene H. Payne was sent by the institute to Bolivia to study existing health conditions and to furnish plans for their improvement. Dr. Payne visited the tropical regions of Santa Cruz, Beni and Pando, where the Bolivian high quality rubber is being produced and where malaria, ancylostomiasis and intestinal infections make any work hard. He studied the needs for medical care in the tin and tungsten ore mines situated high in the Andes as well as in the different towns. He presented an extensive health and sanitation report. The United States and the Bolivian government, through its Ministry of Labor, Health and Social Welfare, agreed on a two years cooperative program. A new, common organization was created under the name of "Servicio Cooperativo Interamericano de Salud Pública" under the direct supervision of the Bolivian minister of health. The program, to be completed by December 1944, included construction of two hospitals in the northern part of the country in the center of rubber production, construction and operation of some ten smaller dispensaries in the adjacent districts, construction of a leprosarium, establishment of several health centers, a central laboratory at Cochabamba, a nursing school and four sanitary launches. An educational program for the public as well as for physicians had to be started

Dr. Payne was appointed chief of the new organization. In 1942 construction of two hospitals with a capacity of 24 beds was initiated in Riberalta and Guayaramerin, with modern equipment including x-ray units and electric light plants as well as the building of a central laboratory to be situated next to the public hospital in Cochabamba, the second largest city in Bolivia.

In 1943 Dr. George C. Gergman of Los Angeles succeeded Dr. Payne as chief. The organization headquarters were moved from Cochabamba to La Paz for a closer contact with the different government authorities. Temporary dispensaries were started in Guayaramerin, Riberalta and Magdalena to cooperate with the Rubber Development Corporation, another agency of the government of the United States, which was anxious to preserve the health of the syringueros (rubber tappers). Dr. Charles von Pohle of the Medical Corps of the United States Army was appointed chief of the medical section.

A new agreement was reached between Bolivia and the United States in January of this year extending participation of the American health mission to December 1947. In April 1945, when Dr. Bergman left for Washington, D. C., A. E. Williamson took charge of the Servicio. The actual chief of the medical department is Dr. Donald H. Eckles of the Public Health Service of Pennsylvania. Among the health projects initiated were a health center in La Paz with a well baby and sick baby clinic, an antepartum and venereal disease dispensary and a tuberculosis survey department, which is still operating without x-ray units. These departments are operated on a part time basis. In the city of Cochabamba a general dispensary

Building of the health department at La Paz, Bolivia. In the same building is also a health center and the headquarters of the Institute of Inter-American Affairs.

with two physicians in charge has been operating for over a year; the building for the central laboratory was finished last year. In Guayaramerin and in Riberalta there are still the temporary hospitals and dispensaries, each in charge of a Bolivian physician. There are some four pharmacist's mates (practicante) stationed at different points, which were selected by the Rubber Development Corporation. A small malaria control group, led by Lieut. Saul Blatman of the U. S. Army, started working in May on a quick survey in Tarija in the southern part of the country and is stationed at Guayaramerin. Free vaccination against smallpox, typhus, typhoid and whooping cough are available at the health center and at the dispensaries.

Projects are under way to provide several towns with a safe drinking water supply and with sewage disposal systems, as well as the installation of x-ray units.

The administrative department has been organized and is under supervision of several American experts. There is also a public relations department, which offers once a week a short talk over a local broadcast station.

Health education was taken over by another agency of the United States government, the Committee of Coordination, which operates independently of the Servicio; interesting movies are shown to physicians and laymen.

The training division of the institute cooperates by granting several fellowships covering such subjects as medical sciences, nursing and sanitary engineering. Some holders of fellowships are already back from study in the United States and are forming the nucleus for the training of others in this country.

Medical service has been provided to people engaged directly in the war effort, promoting health and efficiency of rubber tappers and cinchona bark workers; this is an emergency work of a temporary nature. Other projects for a long term disease control, including hospital construction and malaria survey, are quite promising. To achieve all purposes, actual health work is indeed important, but mutual understanding through personal friendships is essential too, an experience every foreigner who resides for a time in the South has had to learn.

PARIS

(From Our Regular Correspondent)

June 30, 1945.

Interallied Surgical Conferences

The first interallied surgical conference, held on April 30 at the Val de Grace, reunited representatives of the American, English, Russian, Belgian and French health services and revived the tradition of common research and comparison of methods, which had begun so profitably in the course of the last war and which had been taken up again in 1939, but this time without America. Agreements for the general organization of the health service of the armies were drawn up for the American army by Col. Elliot Cutler, for the English army by Brigadier General Porritt and for the French army by Commanding Medical Officer Delvoye. General principles in the treatment of war wounded were presented by Colonel Cutler, Lieutenant Colonel Mitchell and Commanding Medical Officer Curtilliet. Colonel Cleveland, Lieutenant Colonel Eyre-Brook and Commanding Medical Officer Curtilliet presented reports on the treatment of war fractures. Emphasis was placed on the initial care, resuscitation and prophylaxis against infection, as well as on the equipment to be applied from the first lines, among these the pelvipedal (Tobruk) plaster and the thoracobrachial plaster. The discussion resulted in the drawing up of detailed instructions which were distributed widely among the doctors of the Allied armies and which codify the new data on war surgery. The next interallied conference, to be held this month, will consider the treatment of shock, wounds of the chest, abdominal and thoracoabdominal wounds and cranial injuries.

Budget for Public Health

The discussion of the budget for public health in the Consultative Assembly has revealed the lamentable state of health in France after the years of war and famine. The demographic situation, hardly satisfactory in the past, has become more serious. The number of deaths in 1939 exceeded the births by 29,000; the mortality rate was 15.5. Exclusive of the soldiers who died at the front, the prisoners and the deportees, it reached more than 18.0 in the course of the occupation and decreased to 17.0 in 1943. The infant mortality after the winter of 1944 was highest for this century. The morbidity followed the same trend. New cases of syphilis increased fivefold, typhoid fourfold and diphtheria threefold. Tuberculosis, amounting to 224 deaths per hundred thousand in 1930 and 172 in 1939, attained in 1942 the record figure of 234. There is a deplorable shortage of physicians, a catastrophic deficiency of nurses and social workers and lack of medicines. The number of hospitals is inadequate and their equipment is poor.

The minister of health has announced projected reforms, but the needs are of such magnitude that best intentions run the risk of only partial fulfilment. The political upheaval caused by the German occupation, the division of the country into two zones, later its reunion under complete Nazi control, and finally the liberation, have imposed on the legislative arrangements and the projected reforms certain modifications. When the provisional government of General de Gaulle came to power, a decree made a clean sweep of all the laws promulgated under the Vichy régime. But the majority of these laws were put back in force by the new minister. The names changed, but the basis and the doctrine remained unchanged.

The regulation of doctors, which before the war existed only in plan, was carried out under the German domination and has replaced the Confédération des Syndicates médicaux. The corporative idea was then in vogue and the syndicalist conception rejected. The government which then ruled France in the name of the Germans had in mind a program of reforms inspired by German institutions, but a program for which there was not enough time and the execution of which was nullified by the liberation. The present minister, M. Billout, has the task of reconstruction, to which he has applied himself since his entry into the ministry.

Several important features are to be noted in the program of the minister. Medical education is to be improved; the preparation of the physician will be more methodical and better balanced. A more rigid control will replace the liberty formerly enjoyed by the students. A better distribution of physicians over the entire territory is likewise contemplated. At the same time the training of medical aids, particularly of nurses, will be improved, and their social status bettered. Control of physicians created on a new basis, and regulated by the physicians themselves, control of midwives, of dentists and of pharmacists will be the task of the professions themselves. The old syndicates, reconstituted, will devote themselves to professional questions. A check will be established against the "fake" pharmaceutic specialties and the "black market" in medicines. The venereal diseases will be combated by education, prophylaxis, the rational organization of the services and the systematic search for carriers.

In Paris under the jurisdiction of special courts there will be 10,000 children and 30,000 in the provinces. More than 500,000 children do not attend school. These figures have been increasing since the beginning of the war. In a large number of these cases it is a question of temporary disorders associated with the war, the occupation and the famine; but these causes have not ceased to act. The absence of parents and elders, family disruptions, the unbearable material difficulties which have disorganized countless homes, are factors the moral and social disintegrating power of which cannot be measured.

Marriages

William Ferguson Pearce, Baltimore, to Lieut. Mary F. Young of Boston in Chalons-Sur-Marne, France, recently.

Franklin William Mallamo, Fairmont, W. Va., to Miss Dorothy Marie Bowler of Richmond, Va., June 18.

Lionelle Dudley Wells Jr., Holly Hill, S. C., to Miss Verdna Mildred Wohltmann of Charleston, June 28.

Leon Whitfield Robertson, Wake Forest, N. C., to Miss Virginia Mae Lancaster of Rocky Mount, June 23.

Victor T. Scoville, Constantine, Mich., to Miss Henrietta Fruend of Knoxville, Tenn., in Detroit, June 26.

Oliver Aiken Mays, Columbia, S. C., to Miss Anne Marilyn Swicegood of Summerville, March 5.

Edgar Joseph Reagan, Dayton, Ohio, to Miss Rosemary Blanche Stehle of St. Louis, June 16.

James Cuthbert Shecut, Orangeburg, S. C., to Miss Ella W. Lockwood of Charleston, July 2.

Walter Edward Bundy Jr., Oak Hill, W. Va., to Miss Jane Callison of Brooklyn, June 21.

Adolphus W. Dunn to Miss Doris Nash, both of Leaksville, N. C., June 23.

Deaths

David Linn Edsall, distinguished in medicine as a teacher and leader, died in Cambridge, Mass., August 12, aged 76.

Dr. Edsall was born in Hamburg, N. J., July 6, 1869. He received the A.B. degree at Princeton University in 1890, M.D. at the University of Pennsylvania, Philadelphia, in 1893 and the Sc.D. at Princeton in 1913 and Harvard University in 1928. Dr. Edsall, on concluding his postgraduate education in London, Vienna and Gratz, entered the practice of medicine in Philadelphia, becoming immediately associated with the work of the medical department of the University of Pennsylvania, first as associate in the Pepper Clinical Laboratory and subsequently as instructor in medicine, associate, assistant professor of medicine, professor of pharmacology and therapeutics and professor of medicine. In 1911 he went to Washington University School of Medicine, St. Louis, as professor of preventive medicine. From 1912 to 1923 Dr. Edsall served as Jackson professor of clinical medicine at Harvard Medical School, from 1918 to 1935 dean, carrying a concurrent appointment from 1921 to 1935 as dean of the Harvard School of Public Health. He became emeritus in 1935.

In the American Medical Association Dr. Edsall was chairman of the Section on Pharmacology and Therapeutics in 1909-1910, a member of the Council on Pharmacy and Chemistry from 1908 to 1918 and First Vice President in 1919. He held membership in a number of scientific groups, including the Association of American Physicians, American Philosophical Society and the Society for Prevention of Infant Mortality and a retired membership in the Massachusetts Medical Society. He was a fellow of the American Academy of Arts and Sciences and once president of the American Pediatric Society, the American Society for Clinical Investigation and the American School Hygiene Association.

His early war service included activities in a consultant and advisory capacity on many national committees as well as on those organized in Massachusetts. He was a member of the committee on public health of the National Food Administration, a member of a committee appointed by the Working Conditions Service of the Department of Labor to draft a code to protect the health of explosives workers and a member and acting chairman of the committee on health of explosives workers of the National Research Council. He had been a member of a committee of five directed to guide the development of a department of industrial medicine and hygiene at Harvard and served as editor in chief of the *Journal of Industrial Hygiene and Toxicology* when it was created.

Dr. Edsall was noted as an educator and as an investigator. His interests were varied, extending to the industrial and social sides of medicine. One of his most important contributions in industrial hygiene was the discovery of "a disorder due to exposure to intense heat" among stokers on battleships and elsewhere, once known as Edsall's disease. His interest in occupational diseases led to the founding of the Occupational Clinic in the Massachusetts General Hospital.

Hugh Cabot ⊛ Boston, died suddenly while sailing in Fisherman's Bay, Ellsworth, Maine, August 14, aged 73.

Dr. Cabot was born in Beverly Farms, Mass., Aug. 11, 1872, and graduated at Harvard Medical School, Boston, in 1898. He started practice in Boston in 1900, serving on the staff of the Massachusetts General Hospital from 1902 to 1919 and at Baptist Hospital from 1900 to 1919. He was assistant professor of surgery at Harvard Medical School from 1910 to 1918. After a year as clinical professor of surgery he went to the University of Michigan Medical School, Ann Arbor, as professor of surgery, a position held until 1930, serving a concurrent appointment as dean of the medical school from 1921 to 1930. He left Michigan to accept a professorship in surgery at the University of Minnesota Graduate School of Medicine, Minneapolis-Rochester, serving also as surgeon at the Mayo Clinic. Late in 1938 he went to Massachusetts.

Dr. Cabot was a member of the House of Delegates of the American Medical Association from 1911 to 1915 and chairman of its Section on Genitourinary Diseases, 1916-1917. He held membership in the American Surgical Association, American College of Surgeons, American Association of Genito-Urinary Surgeons, American Urological Association and the Clinical Society of Genito-Urinary Surgeons. He was a member of a numerous foreign societies related to his specialty, a member of the founders' group of the American Board of Surgery and a specialist certified by the American Board of Urology. During World War I he was chief surgeon of the Harvard Unit of the British Expeditionary Forces for a year in 1916 and commanding officer the following year; he held an honorary rank of lieutenant colonel in the Royal Army Medical Corps.

Dr. Cabot had been contributing to medical journals since 1900. He was the author of Surgical Nursing, the Doctor's Bill and the Patient's Dilemma and served as editor of *Modern Urology* in 1918 and its third edition in 1936.

During the later years of his life Dr. Cabot waged unrelenting war against the policies of the American Medical Association. He appeared in numerous public forums in opposition and also as a witness for the government in its indictment of the Association under the Sherman Act.

William Linder ⊛ eminent surgeon, died in Olive Bridge, Ulster County, N. Y., August 11, aged 72.

Dr. Linder was born in Beregszasz, Hungary, July 4, 1873, coming to the United States in 1886. He returned to Europe for his postgraduate studies after graduating at Bellevue Hospital Medical College in 1896. He served his internship at St. Catherine's Hospital, Brooklyn, later becoming a member of the gynecologic staff there. In subsequent years he was also a member of the Wyckoff Heights Hospital, Rockaway Beach Hospital and the Israel Zion Hospital of Brooklyn, where he was surgeon in chief. In 1935, to honor his twenty-nine years' association with the Jewish Hospital of Brooklyn, the board of directors elected him "dean of surgery," a special recognition to enable him to remain in active service to the hospital. In 1924 he joined the staff of Long Island College of Medicine, becoming emeritus professor of clinical surgery in 1935. A member of the founders group of the American Board of Surgery, Dr. Linder was a fellow of the American College of Surgeons and of the New York Academy of Medicine and past president of the Medical Society of the County of Kings and the Brooklyn Surgical Society. He spent his winters in Florida, where he was a member of the state medical society and a member of the staffs of the Jackson Memorial, Miami, and St. Francis hospitals, Miami Beach.

Claude Elson Boyd, Amory, Miss.; Birmingham Medical College, 1911; member of the American Medical Association; president of the Northeast Mississippi Thirteen Counties Medical Society in 1933; died in the Baptist Hospital, Memphis, Tenn., June 9, aged 63, of heart disease.

Elizabeth Campbell ⊛ Cincinnati; Woman's Medical College of Cincinnati, 1895; organized in 1909 the Cincinnati Visiting Nurse Association and in 1917 the Cincinnati Social Hygiene Society, serving both as their first president; founded in 1932 the Cincinnati Committee on Maternal Health, serving as chairman; in 1910 vice president of the Cincinnati Academy of Medicine; in 1942 given an honorary life membership in the American Social Hygiene Association, having served as a member of its board from 1925 to 1936 and from then until 1938 as vice president; in 1943 a portrait of her was unveiled at Christ Hospital in recognition of her forty-one years' service as a member of the staff; died June 7, aged 83.

Wilson Thompson Davidson ⊛ Colonel, U. S. Army, retired, Belton, Texas; University of Texas School of Medicine, Galveston, 1896; fellow of the American College of Surgeons; entered the regular army as an assistant in 1901; veteran of the Spanish-American War and World War I; retired with the rank of lieutenant colonel on June 10, 1920 for disability in line of duty; under the Act of June 21, 1930 became a colonel; died in the Veterans Administration Facility, Dallas, May 19, 1944, aged 75, of cerebral hemorrhage and arteriosclerosis.

Carrol William Downey, Tallapoosa, Ga.; Atlanta Medical College, 1898; member of the American Medical Association; died April 8, aged 69.

William Vincent Eckhart, Marion, Ind.; Jefferson Medical College, Philadelphia, 1941; interned at the Atlantic City Hospital in Atlantic City, N. J.; entered the medical reserve corps of the U. S. Army as a first lieutenant on June 6, 1941; began active duty in the medical corps, Army of the United States, on Sept. 14, 1942; placed on inactive duty in April 1945; killed in an automobile accident May 17, aged 29.

John Miles Gibbons, New York; University of Pennsylvania Department of Medicine, Philadelphia, 1899; also a lawyer; retired general counsel of the New York, New Haven and Hartford Railroad Company; died in St. Luke's Hospital May 29, aged 81.

Salada Leon Goad, Marlow, Okla. (licensed in Oklahoma under the Act of 1908); died in Duncan May 25, aged 77.

Smith Gorsuch ⊕ Castalia, Ohio; Ohio Medical University, Columbus, 1902; president of the Castalia Bank; member of the chamber of commerce; served as physician for the County Home; on the staff of the Providence Hospital, Sandusky, where he died May 23, aged 75.

Judge Gant Hambright, Roby, Texas; University of Louisville (Ky.) Medical Department, 1891; member of the American Medical Association; honorary member of the State Medical Association of Texas; died in a Sweetwater hospital May 28, aged 83.

Joseph Austin Hipp ⊕ Olney Springs, Colo.; St. Louis College of Physicians and Surgeons, 1904; died in May, aged 76.

Samuel Hill Howard, Durant, Miss.; Memphis (Tenn.) Hospital Medical College, 1890; died June 19, aged 81.

Algernon B. Kidd, Shreveport, La; Memphis (Tenn.) Hospital Medical College, 1894; died April 24, aged 72.

John Dorsey Knox ⊕ Warren, Ohio, Western Reserve University Medical Department, Cleveland, 1908; fellow of the American College of Surgeons; served during World War I; on the staff of the Warren City Hospital, where he died May 26, aged 63, of chronic myocarditis.

Carl Frederick Lewis, Jerseyville, Ill.; Bennett Medical College, Chicago, 1909; served overseas during World War I; died May 31, aged 60, of coronary thrombosis.

James Everett Maddux, Fulton, Calif.; Cooper Medical College, San Francisco, 1894; died in a hospital at Santa Rosa May 26, aged 81, of carcinoma of the stomach.

Mark Irving Makler ⊕ Lynn, Mass.; Northwestern University Medical School, Chicago, 1927; member of the New England Pediatric Society; on the staffs of the Children's Hospital in Boston and the Lynn Hospital, where he died May 14, aged 42, of Hodgkin's disease.

William C. Marshall ⊕ Yellow Springs, Ohio; Medical College of Ohio, Cincinnati, 1890; served as health officer of Greene County; on the staff of McClellan Hospital, Xenia, where he died May 31, aged 86, of coronary heart disease and arteriosclerosis.

George R. Meyer ⊕ Marshalltown, Iowa; State University of Iowa College of Medicine, Iowa City, 1895; died May 17, aged 74, of cerebral hemorrhage.

Robert Bogie Miller, Cincinnati; University of Cincinnati College of Medicine, 1941; served an internship and residency at the Cincinnati General Hospital; died in the Good Samaritan Hospital May 4, aged 29, of pulmonary tuberculosis

CAPT. VINCENT F. ATENE, M. C., A. U. S., 1913-1942

LIEUT. COMDR. D. H. BRUMBAUGH (MC), U.S.N.R., 1903-1945

CAPT. NEWTON ALEXANDER CANNON, M. C., A. U. S., 1914-1945

George B. Lawrence, Crab Orchard, Ky.; University of Louisville Medical Department, 1891; veteran of the Spanish-American War; died May 9, aged 80, of congestive cardiac failure.

Robert Bruce Miller, Lebanon, Ore.; University of Oregon Medical School, Portland, 1914; member of the American Medical Association; on the staff of the Lebanon General Hospital, died May 31, aged 59, of myocarditis and rheumatism.

KILLED IN ACTION

Vincent Francis Atene, Brooklyn; Creighton University School of Medicine, Omaha, 1938; interned at the Norwegian Lutheran Deaconesses' Home and Hospital; served a residency at the Victory Memorial Hospital and the Brooklyn Cancer Institute, began active duty as a first lieutenant in the medical corps, Army of the United States, on Jan. 23, 1941; promoted to captain; posthumously awarded the Purple Heart and a Presidential Citation; transport surgeon; killed in action in the European theater Dec. 1, 1942, aged 29.

Donald Harmon Brumbaugh ⊕ Redlands, Calif.; Stanford University School of Medicine, San Francisco, 1931; interned and served a residency at the San Bernardino General Hospital in San Bernardino; interned at St. Luke's Hospital in San Francisco; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve on Sept. 28, 1942; assigned as an area surgeon with marine artillery regiments at Camp Dunlap, Niland, Calif.; junior medical officer, U. S. S. *Hamlin,* a seaplane tender, in Tacoma, Wash., from April to September 1944, when he became senior medical officer on the U. S. S. *Birmingham;* received the Bronze Star Medal for action off Leyte in October 1944 while the *Birmingham* was aiding the U. S. S. *Princeton;* died in the Asiatic area May 4, aged 41, of extreme multiple injuries.

Newton Alexander Cannon, Vanleer, Tenn.; University of Tennessee College of Medicine, Memphis, 1941; interned at the Nashville General Hospital in Nashville, Tenn.; began active duty as a first lieutenant in the medical corps, Army of the United States, on Jan. 1, 1943, later promoted to captain; killed in action in Luzon, P. I., March 31, aged 30.

Ellsworth Eurit Moody ⊕ Joplin, Mo ; Washington University School of Medicine, St. Louis, 1914; specialist certified by the American Board of Pediatrics, Inc.; on the staffs of the Freeman and St. John's Hospital; died in Greenup June 10, aged 53, of injuries received in an airplane accident.

Oliver M. Morris, Sheridan, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1897; Indiana University School of Medicine, Indianapolis, 1908; died May 14, aged 76, of carcinoma of the stomach

Beriah Edwin Mossman, Youngstown, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1900; member of the American Medical Association, past president of the Mercer County (Pa.) Medical Society, city physician, served on the surgical staff of the Greenville (Pa.) Hospital; on the honorary staff of the Youngstown Hospital Association; chief of Mercer County (Pa.) Draft Board in 1917; died May 3, aged 70, of coronary thrombosis

Walter C. Myers ⊕ Savannah, Mo.; Central Medical College of St. Joseph, 1897; past president of the Andrew County Medical Society; died April 17, aged 69, of chronic nephritis.

Charles W. Nehl, St. Louis, American Medical College, St Louis, 1903; served as professor of osteosyndesmology and angiology at his alma mater, died April 22, aged 76, of chronic myocarditis.

William B. O'Bannon, Stanford, Ky.; Eclectic Medical Institute, Cincinnati, 1883; member of the American Medical Association; served as a member of the city council and as representative from Lincoln County to the state legislature; died April 22, aged 89.

William Henry Parsons, San Antonio, Texas; Hospital College of Medicine, Louisville, Ky, 1906; member of the American Medical Association; died May 22, aged 69, of cerebral hemorrhage

Artie Blair Paul, Portland, Ore.; Jefferson Medical College of Philadelphia, 1924; member of the American Medical Association; served during World War I; died in the Veterans Administration Facility, Roseburg, May 16, aged 51.

Francis John Pellegrino, Castleton, Vt.; Middlesex College of Medicine and Surgery, Cambridge, Mass, 1936; interned at White Plains Hospital in White Plains, N. Y.; began active duty as a first lieutenant in the medical corps, Army of the United States, on Aug. 24, 1942, with service terminated Sept. 20, 1944 because of physical disqualification; died in Boston May 20, aged 34.

Thomas Clayton Piles, Piedmont, Mo.; Missouri Medical College, St. Louis, 1890; past president of the Wayne County Medical Society; served as county coroner; on the staff of the Poplar Bluff (Mo.) Hospital April 10, aged 82, of chronic myocarditis and coronary occlusion.

George Washington Hull Presnell ⊕ Sikeston, Mo.; Barnes Medical College, St. Louis, 1897; mayor of Sikeston; served as alderman; past president of the Scott County Medical Society; served during World War I; died May 26, aged 71, of leukemia.

Peter Francis Purcell ⊕ Schenectady, N. Y.; Albany Medical College, 1911; served during World War I; on the staff of the Ellis Hospital; died May 2, aged 57, of dissecting aneurysm of the aorta.

Henry George Storner ⊕ Olean, N. Y.; University of Buffalo School of Medicine, 1923; served as a member of the Fifty-Fourth Battery in the Field Artillery Officers Central Training School at Camp Zachary Taylor, Ky., during World War I; on the staffs of St. Francis and Olean General hospitals; died May 15, aged 46, of heart disease.

Benjamin G. Swanson Jr., Atlanta, Ga.; University of the South Medical Department, Sewanee, Tenn., 1907; died in a Savannah hospital March 17, aged 62.

LIEUT. RICHARD CHARLES DIAMON
M. C., A. U. S., 1917-1944

LIEUT. FELICE GEORGE SACCO
M. C., A. U. S., 1918-1945

CAPT. ANDREW CLEVE HEATH
M. C., A. U. S., 1914-1944

KILLED IN ACTION

Richard Charles Diamon, Herminie, Pa., Jefferson Medical College of Philadelphia, 1943; interned at the Lankenau Hospital in Philadelphia; began active duty as a first lieutenant in the medical corps, Army of the United States, on Jan. 14, 1944, assigned to Northington General Hospital in Tuscaloosa, Ala.; killed in action due to air attack in Stalag, Germany, Dec. 23, 1944, aged 27.

Felice George Sacco, New York; Marquette University School of Medicine, Milwaukee, 1943; interned at the U. S. Marine Hospital in Staten Island; began active duty as a first lieutenant in the medical corps, Army of the United States, on Feb. 25, 1944; died January 15, aged 26, of wounds received in action in the Southwest Pacific area.

Andrew Cleve Heath, New Orleans; Louisiana State University School of Medicine, New Orleans, 1941; interned at the Charity Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 1, 1942; later promoted to captain; died of wounds received in Germany Dec. 21, 1944, aged 30.

Correspondence

ELECTROMYOGRAMS OF TREMORS

To the Editor:—In Queries and Minor Notes in THE JOURNAL, July 7, a query appeared about electromyograms of tremors, by George H. Hoxie, M.D., Berkeley, Calif. The answer said that no tracings of the specific tremors described in the query are available in the medical literature. This answer was probably given by a writer who is not acquainted with literature outside this country. As a matter of fact, records of intention tremor were published by me in 1929 (Etude sur les phénomènes oscillatoires dans la sclérose en plaques, Royal Academy of Sciences at Amsterdam, Proc., vol 32, No. 1, 1929). The conclusion was that 80 per cent of so-called intention tremors have to be considered as atoxia instead of real tremors. Senile tremor and tremor of excitement were recorded in other publications. I mention Action-Tremor (*J. Nerv. & Ment. Dis.* **64**:1 [July] 1926; Phénomènes rhythmiques du système nerveux normal et malade, *Rev. neurol.* **1**:367; Tremors and Related Phenomena, *Nederl. tijdschr. v. geneesk.* **1**:472 [Jan. 28] 1928). A very good article entitled "The Nature of Tremors" was published in the *North Carolina Medical Journal* (**5**:15 [Jan.] 1944) by Arthur Allen Morris, M.D., from the Montreal Neurological Institute, Quebec, Canada.

A similar mistake was made some years ago by one of the authors in the reference of the answer to the query. The conception of tremor as a phenomenon of discharge in motor cells of the central nervous system and the pathophysiologic similarity of tremor and clonus was attributed to Wilson instead of to the undersigned.

HERMAN DE JONG, M.D., Durham, N. C.
Associate Professor of Neuropsychiatry,
Duke University School of Medicine.

THE GIANT CELLS IN HODGKIN'S DISEASE—ANCIENT ERROR IN MODERN MEDICINE

To the Editor:—It is difficult to determine just who is responsible for the preservation in modern medicine of the ancient error that the giant cells in the tissues of Hodgkin's disease were first described by the Austrian investigator Sternberg or by Dorothy Reed, an American. As a matter of truth they were first described by an Englishman, Greenfield, in 1878, twenty years before Sternberg called attention to them in 1898 and twenty-four years before the appearance of Reed's paper in 1902 and Andrew's paper at about the same time. Nevertheless these cells are frequently referred to as Sternberg's cells or as Dorothy Reed cells or as Sternberg-Reed cells and practically never as Greenfield's cells. In his presentation to the Pathological Society of London on April 2, 1878 on "Specimens Illustrative of the Pathology of Lymphadenoma and Leukocythemia," Greenfield followed the English custom of using the designation lymphadenoma synonymously with the term Hodgkin's disease. Greenfield stated that, in the microscopic examination of lymph "glands" in lymphadenoma ". . . . the fibrous stroma appeared coarser, and there were a large number of multinucleated cells adherent to the trabeculae, well seen on washing away the lymph cells. These multinucleated cells, containing from four to eight or twelve nuclei, were often collected in clusters in parts of the gland, especially where the fibrous change was progressing." One of his illustrations portrays numbers of multinucleated giant cells which, contrary to the statement just quoted from the text, show no connection with the surrounding fibrous trabeculae. This, however, is neither here nor there—the fact remains that the giant cells in the tissues of Hodgkin's disease were first described by Greenfield. Nor is it of much importance that he regarded them as multinucleated, thus differing from those who subsequently preferred to teach that the giant cells in Hodgkin's disease are mononuclear although multilobular but agreeing, in part at least, with those who believe that both varieties may occur. It seems to me that, if the giant cells in Hodgkin's disease are to be designated eponymously, the accolade should go to Greenfield (Greenfield, W. S.: *Tr. Path. Soc. London* **29**:272, 1878). In the same connection it is interesting to recall that Sternberg interpreted the histologic changes in pseudoleukemia (the German synonym for Hodgkin's disease) as revealing a "peculiar variety of tuberculosis of the lymphatic apparatus." The next year (1899), however, he courageously reversed himself and announced the view that the cause of pseudoleukemia is "still unknown." Although Sternberg's renunciation is seldom mentioned, his original opinion is resurrected sometimes to support the theme that tuberculosis follows Hodgkin's disease "like a shadow."

Hodgkin's disease provides another example of ill bestowed credit in the form of the Pel-Ebstein eponym. In 1887 Pel of Amsterdam and Ebstein of Göttingen independently of each other described a syndrome in Hodgkin's disease characterized by gradual ascent of the patient's temperature to 103 or 104 F., where it is maintained for a period of three or four days, sometimes longer, after which it descends and the patient remains afebrile for an interval of about ten days or two weeks (Pel, P. K.: *Berl. klin. Wchnschr.* **24**:644, 1887. Ebstein, W., *ibid.* **24**:565, 837, 1887). Similar reactions occur with almost predictable regularity over periods varying from several months to a year or more. Precisely the same syndrome was described by Murchison seventeen years previously in a paper which appears in the *Transactions of the Pathological Society of London* under the title of "A Case of 'Lymphadenoma' of the Lymphatic System, Spleen, Liver, Lungs, Heart, Diaphragm, Dura Mater, &c." (Murchison, C.: *Tr. Path. Soc. London* **21**:372, 1870). The histologic examinations were carried out by Burden Sanderson. Neither Murchison nor Sanderson seemed to be any too sure that the disease was an example of Hodgkin's "lymphadenoma." This uncertainty was reflected not only in the title of Murchison's paper, where the word lymphadenoma is in quotation marks, but also in the text, where he refers several times to the resemblance of the disease to "tubercle or cancer." Sanderson's woodcuts depicting the microscopic changes do not bear the slightest resemblance to the histology of Hodgkin's disease as it is now known. On the other hand one of them (page 385) shows microscopic features which are strangely reminiscent of the malignant tumor that is more or less familiarly known to pathologists as perithelioma or perithelial sarcoma, the naked eye appearances of which may resemble those of cancer and the structural unit of which is a small blood vessel. Incidentally, the syndrome in question, contrary to common precept, is not peculiar to Hodgkin's disease but has been noted also in certain forms of caseous pulmonary tuberculosis as well as in necrotic tumors, among them hypernephromas and perithelial sarcomas. Wherever encountered it would appear to be more appropriately referred to as Murchison's syndrome. By all this I do not mean to imply that writers on the subject of Hodgkin's disease are alone in the matter of rendering unto Caesar those things which do not rightfully belong to Caesar. That is by no means true, as witness the fact that Addison described primary progressive (idiopathic) pernicious anemia seventeen years before Biermer, that Parry of Bath described toxic diffuse goiter ten years before Graves and fifteen years before Basedow, that Winiwater, a Swiss army surgeon, described what is currently designated Buerger's disease twenty-nine years before the appearance of Buerger's paper, that Edward Selleck Hare in the days of his house officership at the Stafford Infirmary during the late eighteen thirties described the precise equiva-

lent of the now familiar "Pancoast's syndrome" (superior pulmonary sulcus tumor), including Horner's symptom complex, thirty years before Horner and nearly a century before Pancoast, and so on (Hare, E. S.: *London M. Gaz.* **1**:16, 1838-1839).

DOUGLAS SYMMERS, M.D., New York.
General Director of Laboratories, Department of Hospitals, City of New York.

NODULAR VASCULAR DISEASE OF THE LEGS

To the Editor:—The article "Nodular Vascular Diseases of the Legs," by Montgomery, O'Leary and Barker (THE JOURNAL, June 2, p. 335), should not go unchallenged. The authors have attempted to define a new entity, "nodular vasculitis," and to differentiate it from erythema induratum. Because the authors are eminent, there is danger that their conclusions will be accepted and that an ill defined entity will enter the medical nomenclature to confuse all physicians who are not dermatologists.

In the differential diagnosis between "nodular vasculitis" and erythema induratum they state that the nodules tend to be more painful in the former and that erythema induratum tends to occur in younger women. These distinctions are not valid, for the nodules of undoubted erythema induratum may be extremely painful and may occur at any age. After analyzing their paper, one must assume that they have really only one point of differentiation between "nodular vasculitis" and erythema induratum, and that is the presence or absence of undoubted tuberculous lesions elsewhere in the body.

The senior authors presented a woman aged 54 with a diagnosis of nodular vasculitis before the Minnesota Dermatologic Society in 1943 (O'Leary, P. A.; Montgomery, Hamilton, and Brunsting, L. A.: A Case for Diagnosis, *Arch. Dermat. & Syph.* **50**:212 [Sept.] 1944). The woman had purplish red, deep seated tender nodules of the medial and posterior aspects of the legs from the ankles to the middle of the thighs of five months' duration. In the antetibial areas were healed scars dating from a skin infection of several months' duration during childhood. Her father had pulmonary tuberculosis. A roentgenogram of the chest was normal and the tuberculin test with purified protein derivative elicited a negative reaction in the first dilution. A biopsy from one of the lesions showed obliterative changes in the vessels, areas of epithelioid cells, foreign body giant cells and collections of plasma cells. In the discussion of this case Dr. Montgomery minimized the significance of the presence of the giant cells and epithelioid cells and emphasized the predominance of the vascular changes. Yet six months later, as they state in their article in THE JOURNAL, this same woman presented a histologically proved tuberculous cervical adenitis and a strongly positive tuberculin test.

The various tuberculids which the dermatologist encounters are so typical in their appearance, distribution and clinical course that the detection of other tuberculous lesions are not necessary for a correct diagnosis—and so it is with erythema induratum.

The question as to whether or not there is an entity such as "nodular vasculitis" is of more than academic importance. If one should decide that such a diagnosis is acceptable in a particular patient, then that patient will be offered no other treatment than the wearing of elastic supports of some kind. However, if the diagnosis of erythema induratum is made, the prognosis may be excellent because erythema induratum frequently responds to treatment with tuberculin, gold sodium thiosulfate, neoarsphenamine or one of the newer trivalent arsenicals such as dichlorophenarsine hydrochloride-U. S. P.

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, Aug. 18, page 1188.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: January. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.

ALASKA: Juneau, September. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

ARKANSAS:* *Medical.* Little Rock, Sept. 20-21. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, Nov. 8. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral.* San Francisco, Nov. 11. *Written.* Sacramento, Oct. 15-18. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

COLORADO:* Denver, Oct. 2-5. Final date for filing application is Sept. 17. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT:* *Medical. Examination.* Hartford, Nov. 13-14. *Endorsement.* Hartford, Nov. 27. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, Nov. 13-14. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

DISTRICT OF COLUMBIA:* *Reciprocity.* Washington, Sept. 10. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

ILLINOIS: Chicago, Oct. 9-11. Supt. of Registration, Department of Registration & Education, Mr. Philip Harman, Springfield.

INDIANA: Indianapolis, Aug. 28-30. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

KANSAS: Topeka, Dec. 6. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

MAINE: Portland, Nov. 13-14. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: *Medical.* Baltimore, Dec. 11-15. Sec., Dr. J. T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, Dec. 11-12. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 20-23. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston.

MISSISSIPPI: Jackson, Sept. 26-27. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

MONTANA: Helena, Oct. 1-3. Sec., Dr. O. G. Klein, First Nat'l. Bank Bldg., Helena.

NEW JERSEY: Trenton, Oct. 16-17. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO:* Santa Fe, Oct. 8-9. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Oct. 1-4. Sec., Dr. Jacob L. Lochner, Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, Jan. 1. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: *Endorsement.* Columbus, October. Sec., State Medical Board, Dr. H. M. Platter, 21 W. Broad St., Columbus.

RHODE ISLAND:* Providence, Oct. 4-5. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, Nov. 13. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA:* Pierre, Jan. 15-16. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

TEXAS: Dallas, Sept. 4-6. Sec., Dr. T. J. Crowe, 918-920 Texas Bank Bldg., Dallas 2.

VERMONT: Burlington, March or April 1946. Sec., Dr. F. J. Lawliss, Richford.

WEST VIRGINIA: Charleston, Oct. 4-6. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.

WISCONSIN:* Madison, Jan. 8-10. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

WYOMING: Cheyenne, Oct. 1-2. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: Denver, Sept. 5-6. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: Oct. 13. Address State Board of Healing Arts, 250 Church St., New Haven 10.

DISTRICT OF COLUMBIA: Washington, Oct. 22-23. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

FLORIDA: DeLand, Nov. 3. Sec., Dr. J. F. Conn, Box 655, DeLand.

IOWA: Des Moines Oct. 9: Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MICHIGAN: Ann Arbor and Detroit, Oct. 12-13. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

MINNESOTA: Minneapolis, Oct. 2-3. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis 14.

NEBRASKA: Omaha, Oct. 2-3. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

SOUTH DAKOTA: December. Sec., Dr. J. D. Alway, Aberdeen.

TENNESSEE: Memphis, Sept. 24-25. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

WISCONSIN: Madison, Sept. 22. Sec., Prof. R. N. Bauer, 152 W. Wisconsin Ave., Milwaukee 3.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Optometry Practice Acts: Prohibition of Advertising Concerning Price Upheld.—The National Optical Stores Company operate five "stores" in Wisconsin. Apparently it was claimed that the stores in question merely sold optometrical merchandise, such as glasses, lenses and frames. It appeared, however, that glasses were sold on the prescription of an optometrist or physician and that a physician is kept in a store to prescribe glasses for the plaintiffs' customers under an "arrangement" in which a room is furnished the physician, the physician fixing a fee of $1 or $2 for examining the eyes of a customer and collecting directly from the customer. The plaintiffs, however, guaranteed the physician a specific amount as fees for a specific period. With respect to one of the Wisconsin "stores" an advertisement was inserted in one of the local papers that purported to offer bifocal double vision glasses of a $12 value for $3.88. The ad exhorted its readers to "get the glasses you need at prices you can afford"; that there was "no extra cost" and "no extra charge." A section of the Wisconsin optometry practice act (Wisconsin Statutes, section 153.10) makes it unlawful for any person to advertise directly or indirectly by any means whatsoever any definite or indefinite price or credit terms on lenses, frames, complete glasses or any optometric service or to advertise in any manner that will tend to mislead or deceive the public. Apparently the Wisconsin Board of Examiners in Optometry threatened to institute proceedings under this section and Benjamin D. Ritholz and others, who were copartners operating the stores, brought an action in equity to enjoin the board from prosecuting them for purported violation of that statute. They claimed that the statute was unconstitutional under the Fourteenth Amendment to the United States Constitution, which, among other things, prohibits a state from abridging the privileges or immunities of citizens of the United States or of depriving any person of life, liberty or property, without due process of law, or from denying to any person within its jurisdiction the equal protection of the laws. The trial court issued a judgment declaring the statute void as in contravention of the constitutional provision just noted and enjoined the board from proceeding against the plaintiffs. The board then appealed to the Supreme Court of Wisconsin.

As to the question as to whether or not, as applied to the practices of the plaintiffs, the provision of the optometry practice act prohibiting advertising any price or terms on optometric mechandise or optometric services violated the constitutional provision referred to, the court regarded itself as bound by its holding in *Modern System Dentists* v. *State Board of Dental Examiners,* 216 Wis. 190, 256 N. W. 922. In that case this court upheld certain rules validly promulgated by the Board of Dental Examiners specifically prohibiting advertising essentially the same as the advertising here involved. Ritholz and the other defendants claimed, however, that that case was not in point here because dentistry is a profession and selling glasses and lenses, such as was done by the National Optical Stores, is merely merchandising. But, answered the court, by their own advertising the plaintiffs profess to do more than merely sell glasses. They advertise to sell glasses to fit the needs of the public, which under the provisions of the optometry practice act requires the services of a person licensed to practice either optometry or medicine. Neither of these is mere merchandising. The basis of the rule applicable to dentists is not that they are professional men but that the advertising prohibited to them tends to deceive and mislead the public, and the reason for the rule is as applicable here as there. The instant statute does not purport to affect the mere merchandising of glasses that does not require the services of an optometrist to prescribe them. The plaintiffs may sell glasses that aid sight by merely magnifying or protecting against excessive sunlight. So they may sell stock glasses where the customer fits himself by trying on glasses in the seller's stock on hand. But we do not have to rest the constitutionality of this statute wholly on our previous decision in the dentist case. The evidence in this case shows that the advertising used by the plaintiffs actually does operate to defraud the public. The customers of the plaintiffs are mostly poor persons and by the plaintiffs' own testimony their advertisements are designed to reach "workers, foreigners and Negroes" particularly. They use the advertisements as a lure or bait, or, as they call it, "an inducement" to draw such persons to their stores. The advertisement on its face is dishonest. It manifestly aims and tends to mislead the public and is therefore fraudulent advertising. This conclusion is inescapable, in the court's opinion, in view of the "setup" in the plaintiffs' stores. The "arrangement" between the physician and the plaintiffs constitutes the physician an "employee" of the plaintiffs. By the testimony of the plaintiffs' general sales agent, when a customer arrives he is ushered into a room occupied by the physician employed by the plaintiffs, who proceeds to make the examination of the customer's eyes. When the physician has completed his examination, he writes out what he calls a prescription and demands $1 or, in some cases, $2 for it. If the customer protests the fee on the ground that the advertisement pursuant to which he came to the store represented that there would be "no extra charge" for examination, the physician answers that the fee is not for glasses but for the prescription. This is, continued the court, on its face a mere subterfuge. Nearly all customers "fall for it" and pay the fee. A plain bare fraud is thus perpetrated. The aim and practice of the plaintiffs, as shown by the testimony of their sales manager and by the "Manual of Instruction" to their salesmen, is to sell the customer the highest priced glasses and frames possible to foist on him even though the complete glasses advertised at $3.88 would supply his need as well. This in the case of a customer who is wealthy or is well to do may be good salesmanship, but it is against the public welfare when it is done to the poor or the class of customers whom the plaintiffs mostly serve. And so as to filching a dollar for examination from the class of customers with whom the plaintiffs mostly deal.

While there may be disagreement in the decisions of courts of last resort, continued the court, on the proposition as to whether or not an ordinary trader can be prevented from advertising the price at which he will sell eye glasses, there is unanimity in the court decisions in this field on the proposition that any advertising that tends to deceive or mislead is a fraud on the public and in our view that rule applies to the present plaintiffs. It is quite true that some of the advertising done by the plaintiffs is not within the ban of the statute. But clearly some of it is, and clearly the plaintiffs cannot enjoin all prosecution under the statute when part of its advertising is banned. Nor can they come into court for advice as to what advertisements they may make through seeking an injunction against prosecution for alleged legal advertising. If the plaintiffs are prosecuted under the statutes for advertising that they consider not fraudulent and the prohibition of it by statute therefore unconstitutional they can assert their claim in defense. This constitutes an adequate legal remedy and thus bars an action in equity.

The judgment of the lower court enjoining the enforcement of the section as against the plaintiffs was in effect reversed and the cause was remanded to the lower court with directions to dismiss the bill of complaint.—*Ritholz et al. v. Johnson et al., 17 N. W. (2d) 590 (Wis. 1945).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Unusual Case of Meckel's Diverticulum. S. Gendel and M. G. Beaver. —p. 891.

Causation of Shock.—Experiments were conducted on 38 dogs divided into three groups. The trauma was limited to the right hind limb. No evidence was obtained from these experiments that either a flow of nociceptive stimuli from the injured field or toxin formation is an important contributing factor in the initiation of circulatory impairment or shock which followed. The animals in which the trauma was applied soon after the administration of spinal anesthesia were protected from shock principally by the blockage of the vasomotor and (less importantly) motor nerves, which greatly lowered the blood pressure and limited the hemorrhage to an amount that was too small to produce shock, instead of by blockage of afferent impulses. The maintenance of such a low blood pressure by spinal anesthesia for the prevention of shock during an operation on man is contraindicated, as the amount of anesthetic required would be too toxic. In all the experiments in which shock developed, the local blood loss was large and constituted the main causative factor. There appears to be no indication for the renewal of efforts to prevent shock by the blockage of afferent nerve impulses through the use of local or spinal anesthesia. Indications for the use of local or spinal anesthesia in shock are based on other grounds.

Stainless Steel Wire Mesh in Repair of Small Cranial Defects.—Boldrey says that small cranial defects ranging in size from burr holes to openings approximately 2 inches in diameter have excited little attention and have generally been shrugged off as of no serious consequence. Yet burr holes in the frontal region result in unsightly depressions and may be associated with tenderness. They have sometimes been filled with bone dust or with buttons removed with the trephine, but these bits of bone absorb rapidly and so fail in the purpose for which they are used. Stainless steel wire, when used in the skull, does not show the disadvantages attributed to it when it is used for orthopedic purposes in other bones of the body. Wire used to hold osteoplastic bone flaps in position or in myoplastic craniotomies becomes tightly embedded within the bone as osseous repair takes place. It seemed reasonable that a mesh of stainless steel wire would become anchored in connective tissue and possibly in bone at the edges of a cranial defect. The mesh was tried first in dogs and later the use of both the 0.0065 inch (40 by 40) and 0.0075 inch (28 by 28) screen was begun in patients. During the past eighteen months it has been used for small defects and has been regarded as satisfactory. There have been no ill effects. None of these patients have died or have required further surgery in the same region, so that no human pathologic material is available. When used to cover frontal burr holes, a layer of screen is placed between the dura and the skull before the bone flap is replaced. This remains in position without sutures. Another piece is added outside the skull, as the double mesh seems to give a better cosmetic result. With limitations, mesh appears to offer a safe, adaptable and readily available method of dealing with small cranial defects.

Frozen Human Skin Grafts.—Strumia and Hodge transplanted 41 autogenous split thickness grafts, preserved in the frozen state from one to sixty-one days, at temperatures of minus 20 to minus 25 C. (minus 4 to minus 13 F.), to 3 patients. These grafts resulted in 80.5 per cent permanent takes. Thirty-four control grafts of fresh skin in the same patients resulted in 86.4 per cent takes. The result of grafting does not appear to be affected by the time of storage of the grafts in the frozen state, at least within the experimental limits mentioned. Aside from the possible development of skin banks for homografts, the preservation of split thickness autogenous grafts in the frozen state allows the operator to obtain at one operation large numbers of grafts which may be employed for transplantation at any time later on.

Gastroenterology: Review of Literature from July 1943 to June 1944. W. L. Palmer, D. S. Harman and W. E. Ricketts.—p. 417.

Large Doses of Ascorbic Acid in Vitamin C Deficiencies.—Kynos and her associates studied the effects of large doses of synthetic ascorbic acid on urinary excretion, plasma and whole blood in 26 patients hospitalized for other ailments but judged to be also deficient in vitamin C on the basis of history, clinical signs and low plasma content of ascorbic acid. The efficiency of single doses of ascorbic acid of 100 to 500 mg. was excellent if the plasma level of ascorbic acid was low. Some patients received as much as 1.5 Gm. of ascorbic acid in one day without significant urinary loss, while the plasma content of vitamin C was increased to high normal levels. The total amount of ascorbic acid supplement required to produce a twenty-four hour excretion of 40 mg. or over varied from 0.5 to 2.0 Gm. and the amount required for saturation from 1.5 to 2.8 Gm. Intravenous administration of ascorbic acid resulted in slightly greater excretion in a few cases. The authors observed evidence of a wide individual variation in the renal threshold for ascorbic acid, the probable plasma level for this series being 1.1 and 1.9 per hundred cubic centimeters. It was not demonstrated that a determination of the whole level is superior to that of the plasma level in diagnosing vitamin C deficiency. Patients with low plasma values generally excreted very small amounts of ascorbic acid until the dose had raised the plasma levels above 1.0 mg. Patients having renal involvement or blood dyscrasias responded atypically to ascorbic acid treatment. Although age does not seem to influence the results of ascorbic acid treatment, there seems to be some evidence that sex plays a part. Fluctuations have been observed in the plasma content of ascorbic acid in connection with certain phases of the menstrual cycle.

Migraine Headache.—Torda and Wolff state that distention of cranial arteries induces pain of an aching quality. The speed with which vasoconstrictor agents such as ergotamine tartrate reduce the intensity of the headache approximates the rate of constriction of the cranial arteries. In many patients the headache arises in the distended branches of the external carotid arteries, although any or all of the cranial arteries may be involved in migraine headache. Secondary to pain from prolonged distention of cranial arteries, the skeletal muscles of the neck and scalp contract and become painful. After several hours of such a headache the vessel may appear more prominent and distended. Instead of being collapsible it becomes rigid, pipelike and less readily compressible. Patients may report that after the first hour or two of an attack of migraine the quality of the headache may change in that the initial pulsating or throbbing headache turns into a steady ache. To account for these changes the authors have postulated that after sustained dilatation there occurs thickening or edema of the muscular and adventitial structures. Sections taken from the temporal artery of patients during attacks of migraine involving this structure revealed on microscopic examination that there was thickening of the arterial wall. Since comparable control sections during periods of freedom from headache cannot be obtained, the authors studied the structure of the arteries of the ears of 6 cats after infusion for two hours of 10 cc. of mammalian isotonic solution of three chlorides containing 0.5 mg. of acetocholine bromide per hundred cubic centimeters. Measurements demonstrated thickening of the walls of the infused vessels. Ergotamine tartrate was less effective in constricting arteries with thickened walls than arteries with normal walls. It is suggested that during attacks of migraine the cranial arteries involved may undergo similar changes after prolonged vasodilatation. Such changes may explain the rigid, pipelike texture of the arteries, the steady aching pain and the tenderness of these structures when headache has persisted for many hours. Also these changes may explain the decreased ability of ergotamine tartrate to reduce promptly the intensity of prolonged headache.

Inhalation of Penicillin.—Hagens and his co-workers treated 22 patients with penicillin by the inhalation method. Urine and blood levels showed that the drug is absorbed from the lungs to a sufficient degree. Because of its local effect the inhalation of penicillin may be the method of choice in cases of pulmonary disease. The inhalation of penicillin results in temporary improvement in bronchiectasis, but the condition frequently lapses back shortly after therapy is discontinued. In most cases gram negative bacteria are encountered, so that another antibiotic substance is also necessary, one to which these bacteria are sensitive. Asthmatic patients who have a superimposed bronchial infection with an organism to which they possibly are allergic may be favorably influenced by treatment. Acute pulmonary conditions respond to the inhalation treatment. The method may be used advantageously in the treatment of children and other patients when the intravenous or the intramuscular injections of penicillin are unsuitable.

Microcrystals of Sulfathiazole in Otolaryngologic Practice.—Ornston used microcrystals of sulfathiazole as a 5 per cent or a 20 per cent suspension in isotonic solution of sodium chloride and as a 5 per cent suspension with 1 per cent paredrine hydrobromide in isotonic solution of sodium chloride. He presents his experiences with the microcrystals in the common cold and its complications, in subacute sinusitis, in chronic maxillary sinusitis, in otitis media, in mastoidectomy and in miscellaneous conditions. The local use of microcrystalline sulfathiazole to combat infections of the upper respiratory tract presents the advantages of freedom from mechanical irritation, prolonged action at the site of infection and effective bacteriostatic action. In a controlled series of cases of subacute suppurative ethmoiditis the instillation of drops or the use of displacement showed that the sulfonamide compound reduced the amount and the duration of the discharge and decreased the incidence of complications. In cases of subacute sinusitis other than ethmoiditis, relief was prompt. In 8 of 11 cases of chronic maxillary sinusitis this condition was cured or improved by irrigation and filling with the microcrystals. Twenty-seven chronically suppurating ears were treated with the suspension, blown in through the auditory tube; in 5 the condition was cured and in 4 improved; in 18 there was no improvement. In all of these cases otitis had resisted other therapeutic methods. Local use of the microcrystals in operative wounds resulted in less drainage and tissue reaction and accelerated healing. No foreign body reaction was observed. Local application of sulfonamide compounds may obviate the necessity of oral administration.

Electromyographic Studies in Poliomyelitis.—Hypersensitivity or spasm of muscles has been emphasized as one of the most characteristic aspects of the acute stage of poliomyelitis. Watkins and Brazier studied the influences of single applications of a therapeutic agent on muscle spasm during the first weeks of the disease. All patients were in the early

infectious stage, and studies were restricted to adult patients. Six such patients were available for study. In all, 835 measurements were made, the first test usually being done within a few days after diagnosis had been established. Muscle spasm was measured by quantitation of the electrical discharges released on five seconds of passive stretching by known weights in order to test the effect of twenty minute applications of hot packs, infra-red radiation, luminous heat, short wave diathermy and the intramuscular injection of neostigmine (1.6 mg.) on this electrical component of spasm. Single applications of hot packs, infra-red radiation and diathermy had no effect. Luminous heat and neostigmine caused a decrease in spasm of approximately 25 per cent. This degree of change was not great enough to indicate a specific effect on spasm.

*Role of Bilateral Orchiectomy in Treatment of Carcinoma of Prostate Gland: Report of 82 Cases. W. W. Scott and J. A. Benjamin.—p. 307.

Mass Sulfadiazine Prophylaxis of Respiratory Diseases.—According to Coburn the first objective of this program was to check the rapidly rising respiratory infection morbidity rates in the winter of 1944 by preventing the implantation of pathogenic bacteria in the nasopharynx. Continuous chemoprophylaxis was selected as the most promising control measure. To test the applicability of chemoprophylaxis under controlled conditions and to determine a standard prophylactic dose of sulfadiazine, programs were designed for five large northern training stations with high respiratory disease rates. Groups of trainees were then selected to receive sulfadiazine prophylaxis and comparable groups to serve as untreated controls. Sulfadiazine prophylaxis has been administered to approximately 600,000 naval personnel, and approximately 300,000 similar personnel have been observed as controls. The institution of this measure was followed by a great reduction in the morbidity rates for respiratory diseases. The incidence of respiratory symptoms observed at sick call was significantly lowered. Hospital admissions for respiratory diseases were reduced from rates varying between 5 and 18 per thousand monthly to less than 1 per thousand monthly. Meningococcic infections were eliminated. The incidence of pneumococcic pneumonia was significantly lowered at most naval stations. Morbidity rates for respiratory diseases caused by filtrable viruses were unaffected. The most effective dosage tested was 1 Gm. daily. The administration of 0.5 Gm. of sulfadiazine daily was also found effective and was followed by fewer untoward reactions. Mild, untoward drug reactions were observed in about 0.5 per cent. Severe reactions occurred in 0.01 per cent of men taking 1.0 Gm. of sulfadiazine daily. Sensitization to sulfonamides and the development of sulfadiazine fast respiratory pathogens did not occur.

Orchiectomy in Carcinoma of Prostate.—Scott and Benjamin report the results obtained by bilateral orchiectomy in the treatment of 82 patients in various stages of carcinoma of the prostate gland. In the majority of patients the early response of metastatic symptoms was much more rapid and satisfactory than had been obtained by the methods in common use before its introduction. The early response of urinary symptoms was neither so frequent nor so satisfactory. A small percentage of patients received little or no benefit from this therapy. Most of the patients treated by this method were either dead or had lost its initial benefits within thirty-six months. In view of the discouraging end results following this therapy the authors believe that a follow-up radical perineal prostatectomy should be seriously considered in selected cases when the response to therapy is such that there is a reasonable chance for the removal of all or almost all of the primary lesion. As yet there is no substitute for radical perineal prostatectomy for cancer of the prostate when the patient's condition and the size and location of the lesion at the time of the first examination permit its complete removal.

X-Rays in Diagnosis of Posterior Herniation of Intervertebral Disk.—At the Montreal Neurological Institute and at the No. 1 Canadian Neurological Hospital various methods have been used to diagnose herniation of the intervertebral disks. Since early in 1942 the injection of iodized oil, with subsequent aspiration, has become routine. During part of this period lipiodol has been the medium, but pantopaque is much to be preferred, not only because it is much more easily injected and aspirated but also because it moves more freely. There is the additional advantage that any small amount which may be left in place is gradually spontaneously absorbed. While it is not as radiopaque as lipiodol, it is sufficiently dense for practical purposes. Childe stresses that plain x-ray films should always be made first. These films usually are not diagnostic of such a herniation but may offer suggestive evidence and they help to exclude other lesions. Myelography when properly performed using pantopaque with subsequent aspiration is an accurate and safe method. Multiple disk herniations are not uncommon, and many unsatisfactory results may be explained on this basis if operation is undertaken without previous myelography. Herniation of sufficient size to produce great disability may cause only comparatively small deformities of the subarachnoid space. Hence the use of a relatively large quantity of oil is advisable, and multiple spot films should be made routinely to avoid missing minor deformities not readily seen under the fluoroscope. Myelography reveals that the size of some herniations undergoes change due to such factors as weight bearing, traction, muscular activity, flexion and extension. Herniated intervertebral disks in the cervical region are often complicated by hypertrophic bone formation. Tumors in the lumbar and sacral regions, and occasionally in the cervical region, may produce signs and symptoms which are clinically indistinguishable from those produced by herniated intervertebral disks. Myelography will usually differentiate between a tumor and a herniated disk.

Relief of Asthma by Sulfonamide Therapy.—Bell presents the histories of 2 patients with severe bronchial asthma each of whom was resistant to epinephrine and each of whom had paranasal sinusitis with streptococci as the main organism of infection. Both showed dramatic response to sulfonamide therapy. The first patient, a woman aged 48, was unable to retain sulfanilamide or sulfathiazole but tolerated sulfadiazine. The second patient, a man aged 58, responded to sulfathiazole. The author does not suggest that sulfonamides are a cure for asthma but states that 2 patients received great benefit and in the second patient it appeared to be a life saving agent.

Actinomycosis of Neck Treated with Penicillin—The subject of the report by McCrea and his associates was a man aged 28 who developed soreness in the region of the lower molars A diagnosis of impaction of third molars was made and the teeth were extracted A localized area of induration remained in the soft tissue of the neck There was pain on motion of the right temporomandibular joint The patient developed an ischiorectal abscess, which was drained A subsequent swelling of the lower jaw subsided, but an indurated area persisted in the soft tissues inferior to the mandible Several months later there was an increase in swelling and tenderness The mass in the neck gradually enlarged A sinus developed inferior to the middle third of the right mandibular ramus A culture taken revealed Staphylococcus aureus Penicillin was given intramuscularly in doses of 20,000 units every three hours for three days but caused no appreciable improvement Pus obtained later contained yellow granules which on staining revealed mycelia and clubbing typical of actinomycosis Since small doses of penicillin had failed to effect cure on previous hospitalization, massive doses were now given, 7,000,000 units being administered over a period of fourteen days The initial dose was 120,000 units and the later doses were 80,000 units The status several months after this massive penicillin treatment indicated complete cure

Test Paper for Rapid Estimation of Sulfonamides.—The test described by La Rosa makes use of Ehrlich's reagent, p-dimethylamino benzaldehyde, in the formation of a Schiff base with primary aromatic amines, as first described by Kuhnan in 1938 The test paper contains this reagent with a sufficient quantity of oxalic acid to give a p_H of 2.5 when wet with serum or other biologic fluids By the use of the test paper the level of sulfonamide can be estimated directly in plasma, serum and other clear body fluids without the addition of precipitating or acidifying agents The orange yellow color produced is evaluated by comparison with an appropriate color chart or with colors produced simultaneously from solutions of known concentrations The test paper can be prepared from a good grade of white absorbent paper It can be stored in the dark in covered glass jars for from five to ten days The validity of this method has been demonstrated on 518 blood samples

Hodgkin's Disease—Goldman and Victor report 319 cases of Hodgkin's disease The youngest patient in the group was 5 and the oldest 76 years of age A clinical diagnosis of Hodgkin's disease can frequently be made by palpation of the involved lymph nodes It is possible to count from 3 to 5 nodes in each of the involved groups The nodes may vary in size from 2 to 12 cm As a rule more than one area is involved Thirteen of the authors' patients showed involvement of the sternal nodes, never before mentioned in the literature The skin was involved in 39 per cent of the patients Roentgenographic findings in the chest characteristic only of this disease were never found There was a gradual transition from a bilateral thickening of the hilar areas to a widening of the mediastinum and invasion of adjacent lung fields Hodgkin's disease of the gastrointestinal tract was observed in only 2 patients It was unusual to palpate the spleen in ambulatory patients The abdominal form of Hodgkin's disease was observed in 27 patients They exhibited weakness, loss of weight, intermittent bouts of fever and a more rapid course Collapse of a vertebra may occur without symptoms of spinal cord compression The characteristic changes in the sternal marrow were a polymorphonuclear shift to the right with severe toxic granulation, increased eosinophilia of young myeloid elements and increase in the monocytic series Pregnancy occurred in 11 patients, therapeutic abortions were performed in 3, miscarriage resulted in 1, and the pregnancies were carried to term in the remaining 7 There was no evidence of Hodgkin's disease in the offspring Even under the most optimal conditions permanent arrest of the disease has not been obtained, but useful life has been prolonged for many years The patient should receive the smallest quantity of irradiation that is compatible with relative well-being, just sufficient to cause gross disappearance of involved lymph nodes The authors utilized a voltage of 200 kilovolts, a filtration of 0.5 copper and 1 aluminum, a port of 10 by 15 cm and a skin-target distance of from 40 to 50 cm Voltages that were either higher or lower produced inferior results In addition to the irradiation the patient should receive supportive hematinic therapy

Quantitative Serologic Tests for Syphilis.—According to Weiner and McNamara the true potency (amount of reagin) of syphilitic serums may be determined, as in the Widal reaction, by quantitative titration of the serums. The recent trends in the rapid treatment of early syphilis have stimulated interest in the use of quantitative serodiagnostic tests. Quantitative serologic tests have been found essential to the optimum treatment of early syphilis and useful in the management of latent and tertiary syphilis. They are also of value in the study of suspected false positive reactions and in the interpretation of the status of the newborn of syphilitic mothers. Protracted seroresistance and clinical complications, especially neurosyphilis, occur predominantly in those patients with early syphilis who have experienced mucocutaneous relapse, a phenomenon usually preceded by a persistent rise in the serologic titer. Impending relapse, which is thus detected by quantitative serologic tests, can often be prevented by intensification or modification of the therapy which is being administered. The routine adoption of quantitative serologic procedures in early syphilis is urged. These tests are of more limited usefulness in other phases of syphilis.

Unusual Sequel to Fracture of Odontoid Process: Case Report. H. Davies.—p. 132.

Protection Measurements in Radium Dial Painting Industry.—Jones and Day review investigations that were carried out to determine how far safety regulations were successful in the radium dial painting industry. Owing to their low penetrating power, the alpha rays can cause damage to the tissues only by immediate contact. Although stopped by a few millimeters of most solid materials, the beta rays penetrate several meters of air, giving intense local ionization in the region of the source. The hands are subject to the greatest exposure from these rays. The harmful effects of general body irradiation by gamma rays are well known and the tolerance dose rate of 1 roentgen per week is generally accepted. The safety measures fall into two groups. First, precautions designed to reduce the unavoidable exposure to a minimum and to improve the general conditions of work. Second, direct examination of the operatives for indications of overexposure, entailing on the medical side routine blood testing, inspection of the hands for signs of local effects and attention to the general health of the workers, and on the physical side the wearing of beta and gamma ray sensitive photographic films and tests for radium in the body. Measurements carried out by the authors indicated that workers in most ordinary luminizing factories are not suffering from excessive exposure either from contamination of the atmosphere with radon or radium dust or by the direct action of beta and gamma rays from outside the body. In some cases the ventilation of darkrooms could be improved. Workers with larger quantities of radium, such as in the preparation of luminous compound, are exposed to greater risks. The authors regard the risk of the inhalation of radium dust as particularly important.

Streptococcic Throat Infection.—Vollum and Wilson report an outbreak of scarlet fever due to Streptococcus pyogenes type 11 in a residential preparatory school for boys and an outbreak of sore throat accompanied by cases of scarlet fever due to type 1 in a residential public school for girls. Treatment of healthy and of convalescent carriers with 6 to 12 lozenges a day for five to seven days, each lozenge containing ½ grain (32 mg.) of sulfapyridine and ½ grain of sulfathiazole, had no apparent effect as compared with control carriers receiving either an antiseptic spray and hypochlorite gargle or no treatment at all in clearing the infecting type of streptococcus from the throat. Prophylactic treatment of healthy contacts with 6 lozenges a day had no effect in preventing streptococcic infection of the throat. Observations made on persons sucking

methylene blue tablets showed that only a fraction of the dye was deposited on the tonsils and none on the posterior pharyngeal wall. Lozenges containing sulfonamide drugs are not likely to be of value for the prophylaxis or for the cure of streptococcic infection of the throat.

Penicillin in Wounds of Chest.—Since penicillin has become available, over 500 penetrating wounds of the thorax have been treated. General parenteral treatment with penicillin was used only occasionally and has not supplanted the sulfonamide drugs, which may often be used with less distress to the patient, as they do not involve three hourly injections. Repeated intrapleural injection of penicillin without bacteriologic and radiologic check is unwise. Intrapleural injection of 60,000 units in 6 to 10 cc. (no more) at the end of the first two or three aspirations is advised by D'Abreu and Litchfield; this injection does not replace adequate aspiration. At the general hospital the uninfected hemothorax is treated by aspiration without intrapleural instillations except (1) when there is coexistent chest wall sepsis, (2) when there is pulmonary infection and (3) when at the conclusion of a thoracotomy for foreign body removal air has been drawn off by an artificial pneumothorax apparatus. Local use of penicillin in case of infection is advisable only in cases of infection by penicillin sensitive organisms. Bacteriologic checks are essential. Despite sterilization of an empyema cavity, operative treatment is necessary in certain cases for the purpose of removing clot and preventing excessive deposition of fibrin on the pleura.

Clostridial Infections.—The evacuation of a large group of wounded men from the Western Front from June to October 1944 afforded Cooke and his associates the opportunity of making clinical observations. Cases which showed a systemic reaction and gave evidence of clostridial infection were examined. From 2,680 wounded men a group of 76 cases with systemic reactions have been studied. All but 4 of this group showed evidence of clostridial organisms in their wounds. It is suggested that this group includes the majority of true and potential "gas gangrene" cases. The group has been further subdivided on the basis of the severity of the systemic reaction into four sections of increasing severity, the last consisting of 2 fatal cases. The 2 fatal cases, 7 of the severe and 18 of the moderate group gave a histopathologic picture of clostridial myositis. Possible significant features in the biochemical findings were low blood cholesterol and high urine creatine levels. While the hematologic studies showed evidence of a hemolytic process in some cases, severe hemolysis was not a feature in any case. Flocculation of chylomicrons occurred in a number of cases, but this is not specific for clostridial infection nor can it be attributed to the direct action of clostridial toxins. At necropsy in the 2 fatal cases extensive fat embolism of the lungs and other organs was demonstrated and demyelination was found in the central nervous system.

Fixation of Skin Grafts.—Clark and his associates employed a modification of the method of fixation of skin grafts described by Sano. Instead of withdrawing blood from the patient, they use citrated plasma and instead of Sano's cell extract they use thrombin solution. The plasma used is obtained from blood of a group AB donor. Plasma as supplied by the blood transfusion services should not be used, for this has been treated to remove the clotting elements. The raw surface of the graft is painted with the solution of thrombin before application, and it is then applied to the recipient area, which has been previously painted with the plasma. The authors have used this method successfully in the grafting of over sixty burns. They stress that complete and continuous contact of the skin and the underlying tissues is secured. Oozing of blood is controlled and the skin is fixed in position by means of a medium favorable for tissue growth. The method is quicker, since it largely obviates the need for stitching the graft in position. It is not necessary to obtain blood from the patient before grafting, for the materials are available from the local transfusion services.

*Fatal Air Embolism During Blood Transfusion. E. G. Dolton, E. Gardner and W. D. Wylie.—p. 531.

Fatal Air Embolism During Blood Transfusion.—While a man aged 53 was undergoing an operation for carcinoma of the stomach, blood transfusion was begun through the left saphenous vein at the ankle. After two and one-half hours the blood transfusion, which had slowed considerably, was accelerated by raising the pressure in the bottle by means of a Higginson syringe, in accordance with routine practice. About fifteen minutes later the temporal pulse suddenly became impalpable and the patient rapidly became cyanosed. Inflation of the lungs with oxygen was substituted for the anesthetic mixture, but without improvement. At necropsy the right auricle was punctured under water which filled the pericardium, and from this puncture a number of air bubbles escaped. The inferior and superior venae cavae and the innominate and jugular veins were distended by large and small air bubbles and contained only a little red frothy blood. Though they have found no record of a similar accident, Dolton and his associates think that it can hardly be the first example. Probably some deaths attributed to shock of operation or status lymphaticus are actually due to air embolism, which goes unrecognized because routine postmortem methods do not reveal it. The method of forcing transfusion with a Higginson syringe is dangerous unless constant close supervision is exercised.

Reactions of Perineum of Pregnant Baboon, with Special Reference to Some Aspects of Hormonal Regulations of Pregnancy. Christine Gilbert and J. Gillman.—p. 51.

Effect of Testosterone Propionate on Menstrual Cycle.—Gilbert and Gillman show that testosterone propionate is capable of inducing premature deturgescence in normal baboons when administered in sufficient concentration in the first part of the cycle. The induced deturgescence may be succeeded by premature bleeding, and a new cycle is initiated thereafter. If the induced deturgescence is not followed by bleeding, menstruation may be postponed for ten to fifteen days. There are differences in effects on the normal female baboon between testosterone propionate and progesterone. Unlike desoxycorticosterone acetate, testosterone propionate, like progesterone, is incapable of producing bleeding twice within the span of a normal menstrual cycle. In 2 of the 9 animals testosterone propionate excited a reaction which is similar to that obtained after a single treatment with 5 mg. of estradiol benzoate in the first part of the cycle.

*Functions of Bone Marrow in Some Forms of Chronic Hepatitis. M. Milela.—p. 1.

Bone Marrow in Chronic Hepatitis.—Milela reports microscopic observations on the bone marrow obtained by sternal puncture in 13 cases of chronic hepatitis. There were 4 cases of atrophic cirrhosis of the Laënnec type, 4 of syphilitic hepatitis, 1 of amebiasis of the liver, 1 of Hanot cirrhosis, 1 of Eppinger cirrhosis and 2 cases of chronic ascitogenic hypertrophy of the liver. Erythropoiesis was inadequate in all of the cases. The maturation of the erythrocytes was arrested at the level of the polychromatic phase. Anemia in chronic disease of the liver is apparently due to the toxic action of the diseased liver on the bone marrow.

*Acute Cerebral Edema and Mesencephalic Hemorrhages as Cause of Death in Metastatic Tumors. R. M. E. Carrea.—p. 228.

Acute Cerebral Edema.—Carrea points out the cause of death in intracranial hypertension due to metastatic cerebral tumors. There is either a mesencephalic hemorrhage from cisternal hernia or cisternal hernia alone. Mesencephalic hemorrhage is fatal, whereas cisternal hernia is curable. Cisternal hernia of the temporal lobe is frequent in cerebral tumors. It manifests itself by a sudden appearance of symptoms of acute cerebral edema leading to respiratory difficulty which may rapidly result in respiratory paralysis. Treatment consists in putting the patient to bed with the head at a lower level than the feet. Intravenous injection of hypertonic dextrose solution and continuous ventricle drainage or repeated evacuation by ventricular puncture and transfusions of human plasma are indicated. Hypertonic sodium chloride solution is contraindicated. Failure of the therapy calls for surgical intervention, either section of the neck of the hernia or temporal lobectomy. When respiratory failure occurs just before the operation, artificial respiration should be practiced as long as the heart beats. The author's patient died from an acute respiratory paralysis. The heart continued beating for about ten minutes. Death was due to acute cerebral edema with formation of a huge cisternal hernia at the temporal lobe and an associated mesencephalic hemorrhage.

*Erythroblastosis of Newborn Infants and Rh Factor. M. A. Etcheverry, H. Linares Garzón and J. C. Pereyra.—p. 93.

Erythroblastosis of Newborn Infants.—Etcheverry and his collaborators report observations on a family of 4 erythroblastotic infants. The young parents were apparently normal. The mother had three normal deliveries and an induced abortion. The first child was born with sclerema and had had convulsions from infancy. The 2 following infants died within one and two weeks after birth from acute jaundice and from acute hemolytic anemia. In the course of the fifth pregnancy it was established that the blood of the mother belonged to blood group A and was Rh negative, whereas that of the father and of the child belonged to blood groups O and A respectively and was Rh positive. Anti-Rh agglutinins were not present in the blood of the mother during the first months of pregnancy. They appeared about the eighth month of pregnancy and increased with such rapidity that it was necessary to induce labor near full term. The infant girl was born apparently normal. Her blood was of group A and was Rh positive. The blood of the umbilical cord showed strong reticulocytosis, highly increased indirect bilirubinemia and a scanty number of erythroblasts. Microscopic study of the placenta showed abnormal persistence of the Langhans layer, intraplacental hematoma with erythroblasts, erythroblasts in the chorionic vessels, and edema and hyperplasia of the chorionic villi. The infant exhibited jaundice three hours after birth. Transfusion with O-Rh negative blood in amounts varying between 20 and 50 cc. each was made four hours after birth and at intervals of twelve hours during the first week of life of the infant. She had fever during the first three days and splenomegaly. Jaundice became acute during the first week and then subsided. During the second week of life of the infant transfusion of O-Rh positive blood was administered by mistake. Immediately afterward the infant presented symptoms of acute anemia, which became grave in four days. The hemogram confirmed the diagnosis. The condition was controlled by transfusions of A-Rh negative blood. It was given first daily, then every other day and at longer intervals in doses of 50 to 180 cc. The infant was normal when discharged from the hospital at the age of 3 months. The authors direct attention to the meaning of sclerema in the newborn, which suggests erythroblastosis of the newborn in the family. They also point to the importance of blood transfusion in the therapy of erythroblastosis of newborn infants. Transfusion with Rh negative blood belonging to the O blood group or to the blood group of the infant should be administered.

Paroxysmal Paralytic Hemoglobinuria.—Louw and Nielsen found only 4 cases of paroxysmal paralytic myoglobinuria in the literature. Their case, the first in the Scandinavian literature, was in a boy aged 10, with history of repeated attacks of muscular pain and difficulty in walking since the age of 4, who was admitted for treatment during an acute attack. Spectroscopy showed excretion of myoglobin during the attack, when there was also pronounced creatinuria. The establishment of 8 cases of progressive muscular dystrophy in the boy's family suggests that this disorder and paralytic myoglobinuria may be different forms of the same condition, the latter representing the acute manifestation, the progressive muscular dystrophy the chronic form.

Penicillin Therapy Including Tyrothricin and Other Antibiotic Therapy. By John A. Kolmer, M.S., M.D., Dr. P.H., Professor of Medicine in the School of Medicine and the School of Dentistry, Temple University, Philadelphia. Fabrikoid. Price, $5. Pp. 302, with 22 illustrations. New York & London: D. Appleton-Century Company, 1945.

This monograph constitutes an attempt to correlate the available information on penicillin and other antibiotic agents for the medical and dental professions. With more and more penicillin becoming available for clinical use and with an expanding interest being manifested in antibiotics, such a review is timely. Kolmer has compressed much useful information within the covers of this compact volume. The first half of the monograph is devoted to the basic principles of therapy with antibiotics, with emphasis being placed on penicillin. The section on the principles of penicillin therapy summarizes the present status of the subject very well. In the sections devoted to the clinical use of penicillin for specific infectious diseases some of the recommendations will not be generally accepted. As an example, in the treatment of staphylococcic septicemia Kolmer advises that sulfathiazole should be administered simultaneously with penicillin. It remains to be proved whether this routine therapeutic combination has any advantage over the use of penicillin alone. Certainly there is the disadvantage that sulfathiazole not infrequently causes undesirable reactions and complications. One would also question the advisability of administering staphylococcus vaccine or toxoid to patients who have recovered from cellulitis and carbuncles. It is of interest that the author favors the combined use of the sulfonamides and penicillin in the treatment of several other types of infectious diseases, including streptococcic septicemia. Kolmer favors heparin as an adjuvant therapeutic agent in the treatment of subacute bacterial endocarditis with penicillin. He also would utilize sulfonamide therapy with penicillin in the treatment of this disease. The reviewer is in agreement with his recommendation that sulfadiazine and penicillin should be employed in the therapy of pneumococcic meningitis. An interesting and important development has been the treatment of syphilis with penicillin. That no final conclusions can be drawn at present concerning the optimal doses and ultimate therapeutic effects are reflected in the author's presentation of the subject. He appears to favor the combined use of penicillin and oxophenarsine hydrochloride. It is obvious that the clinician will not feel too confident in employing penicillin for the therapy of syphilis after reading this section.

The monograph is concluded by a discussion of tyrothricin, gramicidin S, streptothricin, patulin, chlorophyll and streptomycin. In his endeavor Kolmer has reviewed the literature on the subject, and references are appended to each chapter. The number of illustrations is relatively small and are not all reproduced too well. The illustration on page 46 is worthless. For those who wish to familiarize themselves with the practical aspects of antibiotic therapy this monograph is recommended.

Constitutional Medicine and Endocrinology. Edited by E. Pulay, M.D., A. P. Cawadias, O.B.E., M.D., F.R.C.P. and P. Lansel, M.D. Volume I. Cloth. Price, 10s. 6d Pp. 99. London: Frederick Muller Ltd., 1944.

This small volume consists of a series of essays on constitutional medicine in general and includes articles on addisonism or the hypotonic symptom complex, pathophysiology of the blood picture, hemopoiesis and constitution and the clinical aspect of the blood sedimentation rate. These are most inspiring and stimulating accounts of a dynamic, functional study of constitution and should be read widely by physiologists, internists and neuropsychiatrists. Their general trend may be gleaned by a quotation from the summary of the introductory article by Cawadias on constitutional medicine, metabolism and endocrinology: "Constitutional medicine, representing the contemporary conception of the internistic subspecialty known first as gastroenterology and metabolism and later as endocrinology and metabolism, is a well defined branch of internal medical research and practice distinct (with the reserve of overlapping inherent in the construction of medical specialties) from the other internistic subspecialties, neurology, cardiology, diseases of the chest, dermatology, epidemiology (fevers). Its object is the consideration in health and disease of the sum total of the chemical reactions through which the body utilizes protein, fat, carbohydrate, minerals and oxygen and of the regulators of these processes (digestive and nutritive regulators, genes, neuroendocrine system and general environmental factors). Its mode of approach to the patient consists in considering primarily the disturbance of the sum total of the biochemical processes and of their regulators, and from this point of departure considering the various organic localizations so as to arrive at the understanding of the whole of the patient and of the patient as a whole. It consists also in thinking not in terms of disturbance (hyperfunction, hypofunction, dysfunction) of a particular system or organ but of rupture of balance of the system integrating and correlating the body-mind. Its diagnostic technic is essentially clinical and in its general lines is based essentially on a careful history, symptomatology and consideration of the total reactions, instrumental and laboratory findings being assessed in the light of the total clinical picture, in the frame of the total reactions. Its therapeutic technic is based on the understanding of these total reactions and forms an endeavor to reestablish the balance of the system of integration of the body-mind through various psychotherapeutic, dietetic, physical and pharmacological procedures. Its special nosographical field is composed of the constitutional diseases known as endocrine-metabolic diseases, i. e. diseases predominantly of the regulators of the biochemical processes. These include the classical metabolic diseases, genetic diseases, neuroendocrine diseases and those digestive and renal disturbances connected with a neuroendocrine and metabolic imbalance. All these diseases must be approached with the special constitutional diagnostic and therapeutic technic, and not one of these groups can be separated from the general body of constitutional medicine."

Pye's Surgical Handicraft: A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of Surgical Dressers, House Surgeons, and Practitioners. Edited by Hamilton Bailey, F.R.C.S.Eng., Surgeon, Royal Northern Hospital, London. Fourteenth edition. Cloth. Price, $6. Pp. 628, with 724 illustrations. Baltimore: William Wood & Company, 1944.

This is the fourteenth edition of a book which has been popular and affectionately regarded in England since 1884. It appears now under the editorship of Hamilton Bailey, whose writings are highly thought of in present day surgical literature. The purpose of the work is and has been to serve as a practical guide to house officers and practitioners in the care of patients. It stresses, chiefly, minor surgical procedures, conditions encountered in the outpatient department and the preoperative and postoperative care of all types of surgical cases. The subject matter covered is extensive, authoritative and up to date. It is divided into eighty chapters written by forty-six contributors, all English, and naturally presents the accepted English point of view. The style and literary quality, in spite of the number of contributors, is uniform and terse and reads easily. A feature of this edition is the unusually large number of excellent and even beautiful illustrations, photographs, drawings and diagrams. These are intended to illustrate the technic pictorially, and they really do enhance the clarity of the text. This edition is an improvement on its predecessors, and the continued value and popularity of "Pye" is assured.

Contribuição ao estudo das gangrenas dos membros inferiores nos diabéticos. Por Hugo Ottati Perlingeiro. [Tese] Paper. Pp. 151, with 55 illustrations. Rio de Janeiro: Jornal do Commercio, Rodrigues & C., 1944.

In this monograph the author presents his experience in the diagnosis and management of diabetic patients with gangrene of the lower extremities. A detailed study of 39 cases is included. Oscillometric studies, histamine tests and Samuel's maneuver of induced plantar ischemia were carried out and found to be reliable. In order to rule out vascular spasm, Landis and Gibson's test and the intravenous injection of sodium nitrite were used, following the technic of Beck and Takats. The patients' conditions did not lend themselves to arteriography, although the author is aware of the value of this procedure in verifying the degree of diminution or occlusion of the arterial lumen.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PATERNITY TESTS

To the Editor:—Please advise necessary data and significance of tests required in legal paternity court procedure. Grouping: Rh positive and negative; Rh' positive and negative; Hr positive and negative; M positive; N positive and negative? Testimony accepted by physician as expert need not require actual performance of tests. M.D., New York.

ANSWER.—The expert called to perform blood tests in cases of disputed parentage must first properly identify the persons presenting themselves for the examination. This is done by having each affix his or her signature to the report forms, at the same time taking a thumb print with the aid of an ink pad. In the case of infants, a foot print or hand print may be taken. Photographs are also acceptable for identification purposes. It is not necessary for all the persons to be tested at the same time, but if they are they should be requested to identify one another. The date when the blood samples are drawn should be recorded, and any persons accompanying those involved in the dispute may be asked to sign the report as witnesses.

Blood tests can be used only to exclude parentage; if the findings conform with the established laws of heredity, this merely means that the individuals in question could be the parents but need not necessarily be the parents. In instances in which an exclusion of paternity or maternity is obtained, it is good practice to repeat the examination on fresh blood samples. Some courts have such reports rechecked by an independent investigator. With the tests now available, a man falsely accused of paternity can be cleared in more than half the cases. A complete test nowadays would include the four blood groups, the subgroups of A and AB, the M-N types, the eight Rh types, the Hr factor, the P factor and the secretor type. Tests on the saliva for the secretor type are usually omitted, however, because the slight additional chance of excluding paternity it affords is not worth the effort entailed in getting the saliva samples (especially in infants) and in testing them. Also the P factor is hardly ever tested for because of the lack of sufficient potent antiserums. As for the remaining tests, the person performing the tests should limit himself only to those with which he has had sufficient experience. Thus the completeness of the report will vary throughout the country, because not every state has physicians specializing in this subject.

Exclusion of parentage results if one or more of the following laws is broken by the results of the tests:

Tests for the four blood groups O, A, B and AB: 1. Agglutinogens A and B cannot appear in the blood of a child unless present in the blood of one or both parents. 2. Group AB parents cannot have group O children, and group O parents cannot have group AB children. Failure of the tests to conform with either of these two laws is absolute proof of nonparentage.

Subgroups of groups A and AB: 1. No child can belong to subgroup A_1 or A_1B unless one or both parents possess agglutinogen A_1. 2. Parents of subgroup A_1B cannot have A_2 children, and parents of subgroup A_2 cannot have A_1B children. The reliability of these tests is not as great as the common blood grouping tests for the following reasons: 1. The subgroups are not fully developed at birth and are difficult to determine reliably until the infant is at least 1 month old. 2. Bloods exist which give reactions intermediate between A_1 and A_2, especially among Negroes. 3. The subgrouping serums give much weaker reactions than the better anti-A and anti-B serums, so reliable results are possible only with considerable experience. Exclusion of parentage by the subgroups should therefore be considered evidence only that parentage is highly improbable and not necessarily impossible.

Types M, N and MN: 1. The agglutinogens M and N cannot appear in the blood of a child unless present in the blood of one or both parents. 2. Type M parents cannot have type N children, and type N parents cannot have type M children. More experience is required for the accurate performance of these tests than for the common blood grouping tests. In the hands of experts, exclusions based on the M-N tests are absolute proof of nonparentage.

Rh types and Hr factor: 1. The factors Rh_0, Rh', Rh" and Hr cannot appear in the blood of a child unless present in one or both parents. 2. Hr-negative parents cannot have children of types Rh_2, Rh", Rh_0 and Rh negative, and parents of types Rh_2, Rh", Rh_0 and Rh negative cannot have Hr-negative children. When the tests are performed by experts, exclusions of parentage based on these new tests are fully as reliable as exclusions based on the common blood grouping tests.

No expert should testify on the basis of tests performed by another person but should insist on performing the tests himself before offering an opinion. In this way he would not assume responsibility for technical or clerical errors of some other individual but would base his conclusions on his own observations. If this is not possible he should qualify his conclusions, depending on the experience and reliability of the person who actually carried out the examination.

Under the present legal system these tests have the same standing in court as any other evidence introduced, and the judge and jury can give them as much or as little weight as they see fit. In states where blood test laws have been passed, the laws give the courts the power to compel persons involved in paternity disputes to submit to blood tests, on application by any party in the action, but the laws do not compel the acceptance of conclusions based on the tests once these have been performed. Therefore, scientific proof of nonpaternity does not guarantee a just verdict, because the verdict in some courts also depends on certain intangible factors, such as the manner in which the lawyer and the physician present the facts to judge and jury, the impression made by the defendant when he testifies, prejudices in the mind of judge or jury against dissolving a marriage, and sympathy for woman and child. In New York City the tests are performed most often for paternity disputes before the Court of Special Sessions, and in an experience with many hundred examinations, conclusions based on the blood tests have invariably been accepted as final.

URINARY INCONTINENCE FOLLOWING HYSTERECTOMY

To the Editor:—About three months ago I did a hysterectomy on a young woman. She made a splendid and satisfactory recovery from her operation and left the hospital about the twenty-first postoperative day, going home apparently well and in good condition. About a week later, four weeks following her operation, she woke up one night and found her bed quite wet and has continued to pass urine ever since. She returned to the hospital about ten days ago; after thorough examination and injection of methylene blue into the bladder, a diagnosis of urethral incontinence was made. Retention catheters have been used and posterior pituitary injection 0.5 cc. has also been given in an endeavor to tighten up the bladder muscles. She has made little or no improvement under this regimen.

R. E. Stivison, M.D., Topeka, Kan.

ANSWER.—Urethral urinary incontinence such as described is probably due to increased sagging of the bladder from a cystourethrocele which may have been present in lesser degree prior to the hysterectomy. For this there is no satisfactory treatment other than a vaginal correction of the cystocele together with reinforcement of the musculofascial supports of the urethra, preferably with sutures of fine silk. It is important to make certain that the incontinence is solely from the urethra, not from a vesical or urethral fistula. Further, before proceeding to operation it is always necessary to rule out incontinence ascribable to tabes or other cord lesions.

CONTACT ULCER OF LARYNX

To the Editor:—What is the best treatment, including climatic treatment, for contact ulcer of the larynx? M. C., A. U. S.

ANSWER.—"Contact ulcer of the larynx" refers to a superficial ulceration localized in the region of one or both vocal processes and involving the underlying cartilage. The chief predisposing cause is considered to be excessive or faulty use of the voice. The recommended treatment includes strict limitation of the voice to a few words a day for a prolonged period, sometimes several months. Removal of granulomatous tissue and superficial trimming of the ulcerated area with sharp cup forceps aids healing and permits biopsy. A warm moist climate is considered preferable to dry air. Other factors to be considered are the correction of faulty methods of voice production, elimination of chronic sinus or throat infection and avoidance of tobacco and alcohol.

INTRAVENOUS UROGRAPHY

To the Editor:—What are the contraindications to intravenous urography? What technical errors and pathologic conditions produce an absent or subnormal dye concentration in the intravenous urogram?

M.D., New York.

ANSWER.—Excretory (intravenous) urography may be contraindicated because of (1) extreme debility, (2) advanced age or (3) the presence of renal insufficiency. In individuals who have a known idiosyncrasy to iodine, the contrast medium should be administered slowly and in limited amounts. However, in most cases the organic form of iodine in the contrast medium causes comparatively little reaction.

Absence or subnormal concentration of the opaque medium in the excretory urogram may be caused either by technical errors or by pathologic renal lesions. The following technical errors may interfere with visualization of the urinary tract adequate for accurate interpretation: (1) inadequate preroentgenographic preparation of the patient, with resulting obscuration of the areas included in the urinary tract, (2) hyperperistalsis with very fragmentary visualization of any portion of the renal pelves or ureters and (3) inadequate amounts of medium injected intravenously, either because of intolerance on the part of the patient or because of diffusion of the injected medium into the extravenous tissues.

The pathologic conditions in the urinary tract which may prevent adequate visualization are (1) reflex inhibition of secretion in the presence of stone in either the kidney or ureter, (2) ureteral obstruction, such as occurs with hydronephrosis or subsequent to obstructing neoplasm in the kidney, ureter or bladder, (3) failure of excretion of the contrast medium caused by various pathologic lesions such as congenital hypoplasia, acquired renal atrophy, diffuse unilateral pyelonephritis, renal tumor and renal tuberculosis, and (4) congenital anomaly such as renal agenesia.

Failure of visualization in one kidney is sometimes observed without one's being able to determine any etiologic factor. Occasionally the renal pelves may not be visualized in one excretory urogram, but when repeated several days later a normal or slightly subnormal visualization may be present for which no adequate reason may be apparent.

A difference in the degree of visualization of the two kidneys is quite common and it may be difficult to determine the cause. Minor differences in degree of visualization may be of no clinical significance. However, when there is a constant, definite difference in concentration of the dye in the two kidneys or ureters, with some increase in size of the renal pelves, calices or ureters, some cause of the stasis usually is present as the result of active or recent factors.

ARTIFICIAL FINGER

To the Editor:—A young woman who is a pianist has lost the distal half of her right index finger. She is anxious to have the missing part artificially restored to enable her to follow her art. Is such a prosthetic restoration available or practical, and if so where can it be obtained?

Charles F. Noe, M.D., Amana, Iowa.

ANSWER.—The loss of only a portion of one finger ordinarily incapacitates a person so little that a prosthesis is not necessary. Most persons so afflicted will not use a prosthesis except for cosmetic reasons, as it interferes with function of the other fingers. The use of such an appliance in an art requiring the sense of touch and pressure and rapidly integrated motions would probably be a detriment rather than an aid.

Prostheses of plastics and latex of good cosmetic quality are available through such manufacturers as the John J. McCann Company of Burlington, N. J., and the John Eschen Company of New York.

MYDRIATIC FOR EXAMINATION OF FUNDUS

To the Editor:—What is the best and safest mydriatic for a general practitioner to use to examine the fundus? It should be quick acting and of short duration.

Joseph P. Sparks, M.D., Manito, Ill.

ANSWER.—A 2 per cent solution of euphthalmine, one drop in the eye every five minutes for two to four instillations, is recommended. Mydriasis is obtained in twenty to thirty minutes, sufficient for a thorough examination of the fundus. One of the great advantages of this drug is that there is but little effect on the ciliary muscle of accommodation (cycloplegic effect) and consequently the patient is not discommoded visually. But it must not be forgotten that the pupil must be contracted with 2 per cent solution of pilocarpine after the examination is completed to avoid the danger of acute glaucoma.

PROBABLE ATOPIC ECZEMA

To the Editor:—A man aged 21, 5 feet 10 inches (178 cm.) in height, and weighing 133 pounds (60 Kg.), has had a dry and cracking skin almost all his life. He has multiple skin reactions, but too many to be true allergies. Dietary treatment has been tried for a long time with no benefit. This last year his hay fever and asthma were controlled by "shots." In previous years he had reactions without adequate protection. He is just getting over a siege of impetiginous infection with fever which responded well to penicillin. The main problem is a tough dry skin. What is recommended for improving the condition of the oil and sweat glands? I would appreciate references. Intake of fats and oils has not helped.

L. E. Blachman, M.D., Cleveland Heights, Ohio.

ANSWER.—From the information given it would seem that this young man has had a generalized dryness and cracking of the skin all his life. Nothing is said about any localization or whether there is any relief during warm weather. The absence of this information suggests that the patient has a xeroderma or ichthyosis. Multiple skin reactions are spoken of and it could be assumed that these were responses to skin tests, but the ichthyotic skin, as a rule, does not give any such reactions. The history of hay fever and asthma suggests the probability of an atopic eczema. The impetiginous infection could be an infection of the excoriations of the latter disease. Atopic eczema is usually a flexural condition, although it can be generalized. It is usually worse in cold weather and has a history of asthma and hay fever in the individual and also in the family.

The condition is an extremely obstinate one and is often an individual problem because the patient frequently has numerous sensitivities to external and internal agents. The condition is well discussed in Becker and Obermayer's Dermatology under the heading of Neurodermatitis. These patients are often sensitive to soap and wool externally and possibly to eggs, chocolate and other agents in the food. The taking of fats and oils will not contribute to the relief of the dryness. The therapy problem is such an individual one that it would be difficult to outline specific treatment in this instance.

WATERY CYSTS OF CONJUNCTIVA

To the Editor:—What is the proper term for the small watery cysts which appear at the palpebral fissure in the conjunctiva over the sclera and consist of little blebs filled with water? They sometimes are single and sometimes appear in a string of four or five or six, each perhaps the size of a pinhead. Sometimes there are as many as ten to a hundred, usually all connected. When one is snipped off all, as a rule, are empty.

F. P. Thompson, M.D., Chicago.

ANSWER.—Such cysts are not uncommon and are usually seen in connection with a mild chronic catarrhal form of conjunctivitis. No particular name has ever been assigned to the condition, although it is described by W. Stewart Duke-Elder (Text-Book of Ophthalmology, St. Louis, C. V. Mosby, 1938, vol. II, p. 1773). As a rule, such cysts lie in the temporal portion of the palpebral fissure, most frequently below the midline, and usually disappear spontaneously as the conjunctivitis is relieved.

DERMATITIS FROM DIESEL FUEL OIL

To the Editor:—Having observed cases of dermatitis apparently caused by contact with fuel oil used in Diesel engines, I wish to learn if there is any prophylactic measure which can be taken to avoid this.

M. A. Stivers, M.D., Middletown, N. Y.

ANSWER.—Fuel oil used in Diesel engines can cause dermatitis by the fat solvent action on the skin of the light petroleum distillates which it contains; it may cause folliculitis and oil acne because of its content of the heavy petroleum distillates.

Prophylactic measures are directed toward keeping the oil off the skin or, if this cannot be done, allowing the oil to remain on the skin for as short a time as possible.

Protective clothing in the form of oil proof rubber gauntlets, oil impervious sleeves and aprons will keep the oil off the skin. Frequent washing of the hands and forearms, compulsory shower baths after work and a daily change to clean work clothes will reduce the time the oil comes in contact with the skin.

The use of suitable protective ointments on the exposed parts gives some safeguard. An ointment with a lanolin base tends to buffer the solvent action on the skin of the light petroleum distillates. An ointment leaving a dry oil repellent film on the skin tends to minimize contact with the oil. Such ointments are on the market.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, William D Stroud, Philadelphia; Vice Chairman, W. O. Thompson, Chicago; Secretary, Cecil J. Watson, 412 Delaware St S E, Minneapolis

SURGERY, GENERAL AND ABDOMINAL—Chairman, Daniel C. Elkin, Atlanta, Ga; Vice Chairman, William D. Andrus, New York; Secretary, Alton Ochsner, 1430 Tulane Ave, New Orleans

OBSTETRICS AND GYNECOLOGY—Chairman, Philip F. Williams, Philadelphia; Vice Chairman, Francis B Carter, Durham, N. C; Secretary, William F Mengert, 2211 Oak Lawn, Dallas, Texas

OPHTHALMOLOGY—Chairman, Frederick C. Cordes, San Francisco; Vice Chairman, Grady E Clay, Atlanta, Ga; Secretary; Robert J. Masters, 23 East Ohio St, Indianapolis

LARYNGOLOGY, OTOLOGY AND RHINOLOGY—Chairman, Louis H. Clerf, Philadelphia; Vice Chairman, Henry B Orton, Newark, N. J; Secretary, Fletcher D. Woodward, 102 E Market St., Charlottesville, Va

PEDIATRICS—Chairman, John Aikman, Rochester, N Y., Vice Chairman, Henry G. Poncher, Chicago; Secretary, Gilbert J. Levy, 188 S. Bellevue Blvd, Memphis, Tenn.

EXPERIMENTAL MEDICINE AND THERAPEUTICS—Chairman, Edgar V. Allen, Rochester, Minn; Vice Chairman, Carl A Dragstedt, Chicago; Secretary, Dwight L. Wilbur, 237 14th Ave, San Francisco

PATHOLOGY AND PHYSIOLOGY—Chairman, Virgil H Moon, Philadelphia; Vice Chairman, J. J. Moore, Chicago; Secretary, Frank W. Hartman, 2799 West Grand Ave, Detroit.

NERVOUS AND MENTAL DISEASES—Chairman, Percival Bailey, Chicago; Vice Chairman, H. Houston Merritt, Boston; Secretary, R. P Mackay, 8 S Michigan Blvd, Chicago.

DERMATOLOGY AND SYPHILOLOGY—Chairman, Clyde L Cummer, Cleveland; Vice Chairman, Dudley C. Smith, Charlottesville, Va; Secretary, Nelson P. Anderson, 2007 Wilshire Blvd, Los Angeles

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH—Chairman, E. L Stebbins, New York; Vice Chairman, C. O Sappington, Chicago; Secretary, W. A Sawyer, 343 State Street, Rochester, N. Y.

UROLOGY—Chairman, Arbor D Munger, Lincoln, Neb; Vice Chairman, Lloyd G. Lewis, Washington, D. C.; Secretary, Grayson L Carroll, 539 N. Grand Blvd, St. Louis

ORTHOPEDIC SURGERY—Chairman, Theodore A. Willis, Cleveland; Vice Chairman, Francis M. McKeever, Los Angeles, Secretary, J. Warren White, 206 E North St, Greenville, S C

GASTRO ENTEROLOGY AND PROCTOLOGY—Chairman, J. Arnold Bargen, Rochester, Minn; Vice Chairman, Martin S Kleckner, Allentown, Pa; Secretary, Sara M Jordan, 605 Commonwealth Ave, Boston

RADIOLOGY—Chairman, Edwin C. Ernst, St Louis, Vice Chairman Barnard P. Widmann, Philadelphia, Secretary, U. V. Portmann, 2020 E. 93d St., Cleveland.

ANESTHESIOLOGY—Chairman, Ansel M. Caine, New Orleans, Vice Chairman, Harold C. Kelley, New York, Secretary, John S Lundy, 102 Second Ave, S W, Rochester, Minn

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, MAY—AUGUST 1945

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1933. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 1304.

CARCINOMA See Cancer
CARDIAC See Heart
CARDIOVASCULAR DISEASE See also Blood Vessels, Heart disease
gastrointestinal conditions simulate or aggravate, [Clark] *352
Hypertensive See Blood Pressure, high
renal, in retired Army officers, [Levy & others] *1061
treatment at spas, [Comstock] *1023
CARDIOVASCULAR SYSTEM See also Arteries, Blood Vessels, Capillaries, Heart, Veins
insufficiency in paroxysmal tachycardia, [Wolff] 1052—ab
CARDITIS See Heart inflammation
CARIES See Teeth
CAROTID Artery See Arteries
CARPUS See Wrist
CARRIERS See Disease carriers (cross reference)
CARTILAGE epiphysial, transplantation, [Wenger] 544—ab
CASE Finding See Tuberculosis
CASEIN, Hydrolysate of See Amigen
CAST, plaster, for low back pain, [Hauser] *92
CASTRATION See also Testis excision
surgical, x-ray or radium in breast cancer, [Adair & others] *161
de CASTRO, A, personal, 610
CASUALTIES See Accidents, World War II casualties
CATARACT congenital, after rubella in mother, [Perera] 54—ab
myotonia atrophica, [Thomasen] 1055—ab
CATGUT, alcohol to sterilize, 773
CATHETER, aspiration of secretions during lung surgery, 1037
Technic See Anesthesia spinal
CATHOLIC Hospital Association *Hospital Progress* 25th year, 606, 1028—E
CAUDAL Continuous Anesthesia. See Anesthesia
CAUSALGIA, [de Takats] *699; [Mayfield] 1129—ab
CAUSTIC Soda See Sodium hydroxide
CAVAL Veins See Vena Cava
CECUM See Medicolegal Abstracts at end of letter M
CELIAC DISEASE, duodenal drainage in steatorrheas, [Phillipsborn] 235—ab
CELLOPHANE tube, artificial kidney, 288—E; (use of living serous membrane instead) [Rosenak] 750—C
CELLS See also Blood cells, Tissue
giant, in Hodgkin's disease, [Symmers] 1248—C
sources of antibodies, 1232—E
CELLULITIS, necrotic suppurative, of leg, refrigeration treatment, [Kross] *19
CELLULOSE, oxidized absorbable with thrombin as *hemostatic*, [Uihlein] 905—ab
CEREBROSPINAL FLUID, chlorine ion in, [Karlstrom] 1192—ab
myelocytes and normoblasts in, 64
penicillin treatment effect on, [Gammon & others] *653
permeability quotient of sulfathiazole, [Andersen] 470—ab
tests for syphilis in malaria, [Brandt] 152—C
CEREBROSPINAL MENINGITIS See Meningitis, cerebrospinal epidemic
CEREBROSPINAL SYPHILIS See Neurosyphilis
CEREBRUM See Brain
CERVICITIS, CERVIX uteri See Uterus
CESAREAN SECTION, deliver quadruplets under continuous spinal anesthesia, [Uller] *183
CEYLON, number of practitioners, 341—ab
CHAPIN Award See Prizes
CHARNES, MARCOS, Chilean named to International Labor Office, 147
CHARTER See United Nations
CHARTERIS, Major, aids blinded war prisoners, 822
CHEMICALS, Burns from See Burns
dangerous, manufacturers standardize labeling for, 448—OS
industrial hazards, U S bulletins on 1181
President Truman warns that they should remain on critical list, 522—OS
CHEMISTRY See also Chemicals Microchemistry
A M A Council on See American Medical Association
Gibson Island conferences, 957—E
CHEPLIN Laboratories use of telegrams to sell penicillin, 132—E
CHEST See Thorax
CHEWING Gum See Gum
CHICAGO cancer committee opens information bureau, 741
Industrial Health Committee, 818
University of See University
CHICKEN See also Eggs
mites vector for equine encephalomyelitis, 443—E
soup with vegetables for infants, Beech-Nut brand, 1025
CHILBLAINS See Pernio
CHILDBIRTH See Labor
CHILDREN See also Infants, Maternity, Paternity, Pediatrics, names of specific diseases
abdominal pain in, A M A Section on Pediatrics Symposium 127, [Brennemann] *691, (correction) 1141, [Rattner] *696, [Gitlow] 1148—C, 128 [Campbell] *326, [Strauss] *330
activity group therapy for, 606
Adoption See Adoption
body mechanics at different ages [Hansson] *951, *952
Camps for See Camps
convulsions in, 1132
Crippled See Crippled
diet for, pseudodoxia pediatrica, 955—E
Growth of See Growth
guidance institute, N Y, 43
Illegitimate See Illegitimacy
intelligence and sex, 957—E
school, detecting tuberculosis in, Minneapolis, [Myers & others] *852
school, heart disease and rheumatic fever in, [Sampson] 386—ab
school, nutrition survey, Florida, 1233—F
tonsillectomy and myringotomy indiscriminately, 955—E
U S Children's Bureau, (new regional director John F Belz) 455, (general principles on adoption) 955—E (authority under Maternal and Child Welfare Act of 1943) 1101—E, (Bureau analysis) 1112—OS
Welfare Act of 1943 (S 1318), 1028—E, 1036, 1101—E, (Bureau analysis) 1112—OS
welfare, care in liberated countries by UNRRA 1118
welfare services in rural districts, Peru, 965
welfare services urge expansion, U S, 741
CHINA, aid to 379
leprosy in 18—ab
medical and health experts sent to 521
National Institute of *Physiology*, 821
U S Army Medical Corps convalescent camp in, 887
CHIROPRACTORS, basic science certificates issued to, *123, *124
urge passage of Murdock bill to amend U S Compensation Act, 453
CHLORIDES. See Ethyl Chloride, Sodium *chloride*
CHLORINATED nitrils, toxicity, 1132
CHLORINATION, superchlorination of water to control epidemic hepatitis [Neefe & others] *1076
CHLORINE gas poisoning positive pressure respiration in [Hardy & Barach] *359
ion in cerebrospinal fluid, [Karlstrom] 1192—ab
CHLOROAZODIN (azochloramid) treatment of empyema, [Rudensky & others] *573
surface active saline mixture, N N R, (Wallace & Tiernan) 1229
